LONDON has a band of ambitious medical reformers, which is organized under the name of "The Committee for the Suppression of Electrical Quackery." There is a great field before it.

WASHINGTON'S MEDICAL HISTORY.—General Washington was a man six feet two inches high; large-boned, vigorous, and, until the latter part of his life, free from much physical ailment. He had the small-pox when a young man, and his face remained pitted. During Braddock's campaign, in 1755, he had a fever, which Dr. Craik relieved by James' powders. After this campaign he suffered from repeated attacks of dysentery and fever. Washington was apparently not in vigorous health when he became President, and about this time of year, one hundred years ago, he was suffering from "anthrax," or carbuncle, which for a time seriously threatened his life. He died finally, as is well known, from suppurative tonsillitis and laryngeal œdema. Regarding this the *Boston Medical and Surgical Journal* says, pertinently: "The recent strictures of a metropolitan journal upon the medical profession of his day for having hastened Washington's death, while very likely true so far as the main question, that of bleeding, is concerned, will nevertheless bear the comment that venesection was so far a measure of domestic treatment at Mount Vernon that Washington had had himself bled by his overseer before the doctor's arrival, and considered the amount of blood drawn by that functionary — eight ounces — entirely inadequate." Washington's most favored and constant medical attendant was Dr. James Craik, a Scotchman, and an army surgeon.

PRIZE WINNERS.—The Parkes triennial prize of £100 and a gold medal has been awarded to Surgeon R. H. Firth, for the best essay "On the Etiology and Prevention of Yellow Fever." Mr. Jonathan Hutchinson, Jr., F.R.C.S., has gained the Jacksonian prize of the Royal College of Surgeons of England, 1888–89. The subject of the prize for 1890 is the "The Nature and Treatment of Injuries to the Spinal Column, and the Consequences arising therefrom."

SPIRITS OF CHLOROFORM INHALATIONS and spirits of chloroform locally are claimed by Dr. Clemens to cut short attacks of acute rheumatism.

THE TREATMENT OF HÆMOPTYSIS.—Dr. Böttrich, of Hagen, finds opium, with acetate of lead, the most efficacious when bleeding from the lungs has just set in. It combines the action of hæmostasis and diminution of the cough. After two or three days he gave instead hydrastis, which drug he ordered from the beginning when the hemorrhage was only slight. It had mostly a very decided effect. In one case of hysteric hæmoptysis its administration entirely stopped hemorrhage after the first week. Also in cases of frequent bleeding from the nose, hydrastis proved very serviceable, not against a single attack of profuse epistaxis, but against repeated recurrence of the bleeding. In such cases he has used the drug for the last two years, and he is very well satisfied with the results.

THE EPILEPTIC HOSPITAL at Baldwinsville, Mass., has received a grant of $50,000 from the State.

THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF PENNSYLVANIA held its one hundred and fifteenth Annual Commencement on May 1st, and graduated a class of one hundred and twenty-eight physicians and fifty-eight dentists.

"THE ABOLITION OF THE CORONER IN MASS." is the somewhat curious title of an article announced from Mr. Tyndale, of Boston. There is a feeling in this city that the abolition of the average coroner in mass or in detail would be a great boon to society, though it would leave one less place for the "boys."

FROM ART TO SEWAGE.—"It seems to me," muses one of the characters in "Robert Elsmere," "that in my youth people talked about Ruskin; now they talk about drains."

THE SUM of $8,000 has already been collected for the Langenbeck Memorial.

THE NIGHT-SWEATS OF PHTHISIS can be controlled, it is said, by eight to ten grains of sulphonal.

MEDICAL JOURNAL SYNDICATE.—A combination has been effected between the *Medical Register*, *Philadelphia Medical Times*, and *Dietetic Gazette*, Dr. J. V. Shoemaker retiring from the editorship of the *Register*, owing to the pressure of other literary work. Dr. Waugh, editor of the *Times*, will assume editorial control of the *Times and Register*.

SOMETHING FOR EVERYONE.—In these days of persistent office-seeking—when there are many more applicants than there are offices to distribute—we are reminded that when Abraham Lincoln was President he was taken ill, and the physician told him he had varioloid. "What is it?" he asked. "Varioloid," said the doctor. "Good enough," said Lincoln; "I've something now I can give everybody."

"THE KANSAS MEDICAL JOURNAL" is the title of a new medical journal recently published at Topeka. It is edited by Drs. W. L. Schenck, J. E. Minney, and S. G. Stewart.

AN ASCETIC SOCIETY.—The North Carolina State Medical Society, which met at Elizabeth City on April 16th, respectfully declined to go on an excursion or attend a banquet tendered by the citizens of the town. We are pleased to note the devotion to pure science shown by our Southern brethren.

THE TENNESSEE STATE LEGISLATURE has enacted a law regulating the practice of medicine.

THE TWENTY-SECOND ANNUAL MEETING OF THE CANADIAN MEDICAL ASSOCIATION will be held at Banff, N. W. T., on the 12th, 13th, and 14th of August next.

THE CINCINNATI ACADEMY OF MEDICINE is reported to have had a little trouble lately on account of the presence among its members of some lady physicians. At a recent meeting of the Academy, a report was made by a gentleman on the radical cure of hernia. At the close he wished to show three male patients on whom he had operated successfully. Two "lady doctresses" were present, and the men positively refused to exhibit *themselves* till the ladies absented themselves. The president requested the ladies to retire, which they did. One of them, however, on returning asked the cause of her being obliged to withdraw. Despite explanations the lady was unsatisfied, and said if women were not allowed all the privileges of the Academy she thought they should pay only two dollars annual dues instead of three.

PROLONGED GESTATION.—Dr. L. Mervin Mans, U. S. A., reports (*New York Medical Journal*) a case of prolonged gestation which he believes authentic. The period of pregnancy, calculating from the time of last menstruation, was 334 days. At the end of this time the patient bore a healthy male infant weighing nine pounds. This almost breaks the record, though Simpson mentions a case in which delivery occurred 336 days after menstruation ceased. Playfair places the extreme limit at 295 days.

THE SAMUEL D. GROSS PRIZE.—The first quinquennial prize of $1,000, under the will of the late Samuel D. Gross, M.D., will be awarded in 1893. The conditions annexed by the testator are, that the prize "shall be awarded every five years, to the writer of the best original essay, not exceeding one hundred and fifty printed pages, octavo, in length, illustrative of some subject in surgical pathology or surgical practice, founded upon original investigations; the candidates for the prize to be American citizens." It is expressly stipulated that the successful competitor shall publish his essay in book form, and that he shall deposit one copy of the work in the Samuel D. Gross Library of the Philadelphia Academy of Surgery. The essays, which must be written in the English language, should be sent to Dr. J. Ewing Mears, 1429 Walnut Street, Philadelphia, before June 1, 1893.

WHAT IS A LAST ILLNESS?—The French courts were recently called upon to determine the exact sense to be attached to the expression "last illness." The question arose on a claim made on the estate by the medical attendant on the wife of a tradesman who, shortly after the treatment and recovery of his wife, was declared bankrupt. According to the French law, the bill for attendance on a person during his "last illness" is privileged to take precedence, but the trustee contended that the "last illness" referred only to the malady culminating in death. The doctor, on the other hand, urged that the expression should be taken to mean exactly what it says and nothing more, and after full consideration the tribunal ratified his view, and gave judgment in his favor.—*Medical Press and Circular*.

Society Reports.

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND.

Ninety-first Annual Session, held at the Hall of the Faculty, Baltimore, Md., April 23, 24, 25, and 26, 1889.

JOHN MORRIS, M.D., PRESIDENT, IN THE CHAIR.

FIRST DAY, TUESDAY, APRIL 23D.

THE PRESIDENT'S ADDRESS.

AFTER greeting the members, he said that the Faculty was now celebrating its ninety-first birthday, and that he had watched its career for nearly a half-century, and was the only surviving member who had entered its gates by examination. He then addressed the members on the following subject:

THE PHYSIOLOGY AND PATHOGENESIS OF CRIME; HOW FAR CAN MEDICAL MEN AID IN ITS PREVENTION?

The teachings of the day appeared to be to make the physician a naturalist—a physicist. In studying these sciences, the higher study should not be neglected—the study of society—the study of man and his relations to his fellow-men, the advancement of the race through its psychical cultivation. Millions of diseased men remain uncared for, and the causes that have led to their degeneration are overlooke and unstudied. Physical culture is studied in the schools, but the character is not built up. We attempt to reform criminals, to rehabilitate them, and ameliorate their condition. We should use prophylaxis. To prevent a man from becoming a criminal, we must begin with him as a child. There is nothing practical in our moral and religious education. Even the sense of right and wrong is not clearly, effectively, and practically taught. It is only the education that seeks to stimulate every noble purpose and capacity that can avail to form or change character, and this kind of education is not obtained in the school and the church. Everyone cries out against immorality, but no steps are taken to create morality, to make morality a public sentiment, to make it a subject of national pride. Yet these are the prominent, the prevailing influences in Japan. There, crimes of violence and outrage are scarcely known.

Where the law of heredity is recognized, it is the duty of the medical man to forewarn parents, and to suggest the proper education and surroundings to render innocuous this taint of blood. This law of heredity obtains even more in moral than in physical traits, although these latter also, as is known, can be transmitted. "Breeding back" would often render a happy change in our economy. "Begin with a man's grandfather, if you wish to reform him." The family doctor has disappeared, but he must be brought back to occupy a higher and a wider field. We are born with unalterable tendencies, which are not always evil. The Jew and the Gypsy are examples of unalterable types. Psychology rarely enters into the education of a physician, and yet all cases of moral responsibility are associated with it. Ordinarily the physician treats the body alone, irrespective of the mental organization. He is but half a physician. The body yields to the mind, the mind to the body rarely. The weakness or total absence of certain powers of mind is rarely noticed in children, and yet this observation is of the highest importance in shaping their future lives. The physician should be consulted in regard to the education of a family of children, and to do this he must have been trained by a long course of mental observation.

No man is born a criminal. We are not taught to value the truth. Perjury is the most common crime in our country, and yet it is rarely punished. The Church and State have done little to regulate marriage, except the Roman Catholic Church and the Church of England. Marriage should be regulated by law. Paupers and criminals should be prevented from marrying. The Legislature of Kentucky has a bill now before it to regulate marriage. The tramp and malingerer should be stamped out; they need not exist. It is as harmful to bring insane children into the world, as it is to drive them insane by bad usage. The habitual criminal, man or woman, should be deprived of the power to procreate.

In all our original research, let us not forget these questions. Let it be directed to the foundations of life; to the evolution and structure of character; to the evolvement and building up a higher intellectual and moral constitution of the race; not to a childish search after pebbles and toys, of jackstones in place of the true gold. In any and every event our work will go on—our profession will live as long as the ages endure. The more we advance in knowledge, the more the world will need us. As the astrologist, the alchemist, the barber of the middle ages, gave place to the pompous and pedantic oracle of the seventeenth and eighteenth centuries, with his latinity, his lancet, and his squirt—the last like the spear of Telamon which healed at one end the wound inflicted by the other; and as the oracle was followed by the man of the present time, with his ologies and marvellous nomenclature, his thousands of drugs, his hypodermatic syringe, and his microscope seeking after the unseekable; so in the future this present man will be succeeded by a race of men of advanced thought, of truer convictions, of stronger culture, of higher and broader views, to the end that the State may be enlightened, society improved, humanity benefited, and religion exalted.

SECOND DAY, WEDNESDAY, APRIL 24TH.

THE ANNUAL ORATION

was delivered by PROFESSOR WILLIAM OSLER, fellow of the Royal College of London, late of the University of Pennsylvania, and recently elected Professor of the Practice and Theory of Medicine of Johns Hopkins University.

He spoke principally of the need of State Boards of Examiners to decide on the fitness of medical graduates to practise. He said: "In this country a man can follow the vocation he pleases, subject only to such restrictions as may be necessary for the public welfare. The right to regulate the practice of medicine rests with the State, and I believe it is everywhere acknowledged that this right comes within that general public power which extends protection to the lives and limbs of the citizens. At present this power is very variously exercised in different States. In many, no regulations whatever exist. Anyone who wishes, irrespective of qualifications, can practise. In a majority of States, however, there are restrictions which demand evidence on the part of the practitioner that he has studied for a longer or shorter period at an incorporated school. Practically, the rule prevails that, with a diploma from a chartered school, he can begin at once, without any hindrance other than that relating to registration. The educational duties of the State do not here extend beyond the system of common and normal schools, though in a few, higher university works are also undertaken. Special education does not receive support from the public revenues. Schools of law, medicine, engineering, theology, all the special branches of study, are private enterprises chartered by the State, and maintained by fees from pupils or by the munificence of private friends. Certain privileges are granted to these institutions by the State, the most important of which, in the medical school, is the recognition of the diploma as a qualification for practice. So unsatisfactory, however, has this system proved, that there is, on the part of the public and the profession, a growing sense of the necessity for a radical change, as shown by the number of States in which bills have either been already passed, or have been before the legislatures, dealing with the problem.

"It is universally conceded that the basis of legislation is the necessity of protecting the people against the depredations of ignorant graduates and of quacks. The aim is to provide a minimum standard of qualification to be required of all persons who desire to follow the calling of physician or surgeon.

"If we look around upon those engaged in the practice of medicine, we find that an overwhelming proportion belong to the regular or so-called old schools; a second small division profess to follow Hahnemann; while a third, still smaller, neither one thing nor the other, but a little of both, profess a judicious eclecticism. These three bodies have schools, medical journals, and in each State have a more or less complete organization. In the sight of the law all are equal. This unhappy division of the body medical is not limited to professional matters, but is complicated with ethical questions of the highest moment. The outcome of it all has been that there are hostile camps and bitter war.

"The homœopathists and the eclectics will, I think, concur in the necessity for a full and proper curriculum of study in the great branches of medicine, and know no 'isms.' The differences only become glaring when we touch the subject, in which among members of each of the so-called schools the greatest individual differences of opinion exist. The divergence of opinion on this one branch separates absolutely the different classes of practitioners from each other. I do not say that this should not be so. Antiquated dogmas are professed in opposition to a rational and free science.

"We cannot, however, escape from the important fact that, in the eyes of the law, we stand equal, and if we wish legislation for the protection of the public, we have to get it together, not singly. I know that this is gall and wormwood to many, but it is a question which has to be met fairly and squarely. When we think of the nine or ten subjects we have in common, we may surely, in the interest of the public, bury animosities and agree to differ on the question of therapeutics. In connection with license to practise there are, it seems to me, three courses open:

"First. A continuance in the plan at present prevailing, which makes the college the judge of the fitness of the candidate, and State supervision is only so far exercised that the diplomas are registered if from legally incorporated schools.

"Second. The appointment by the State, or by parties so deputized, of a board of examiners which shall, irrespective of diplomas, examine all candidates for the license.

"Third. The organization of the entire profession in each State into an electorate, which shall send representatives to a central parliament, having full control of all questions relating to medical education, examination, and registration. These various plans are at present in operation in different parts of the continent. Colleges have practically had a monopoly for years, as the diploma has carried with it the privileges of registration. To all intents and purposes, the medical schools of the country are private organizations, and have direct pecuniary interests in the size of the classes. These chartered corporations are wholly irresponsible, without supervision by the State, the profession, or the public. It would not be difficult, without fear of just rebuke, to bring a railing accusation against them for persistently acting in their own interest, and not in the interest of the public, but the time has passed for this. Yet it is surprising to think that so many men, distinguished in every way in their profession, cultured and liberal, still cling to, and even advocate, the advantages of an irresponsibility which has made the American system of medical education a by-word among the nations."

At the conclusion of the oration the faculty, upon a motion of Dr. Morris, and after remarks by others, tendered Dr. Osler a vote of thanks. He replied in a few well-chosen words, and said he was glad that his lot was cast in Baltimore.

SECTION ON SURGERY.

RANDOLPH WINSLOW, M.D., CHAIRMAN.

THE CHAIRMAN called attention to the subject of

SURGERY OF THE CENTRAL NERVOUS SYSTEM,

and dwelt first on the importance of understanding thoroughly the general and topical anatomy of the brain, and then referred to the important results obtained by experiments on animals, by clinical observations, post-mortem examinations, and by electrical stimulation of the exposed human brain, during the performance of surgical operations. The cortex and base are most accessible and amenable to surgical procedures. Tumors of the brain are of more frequent occurrence than general practitioners think. W. Hale White and Victor Horsley have done the best work here. Cranio-cerebral topography is a new and very important study, and has been mainly used with surgical treatment of epilepsy, brain abscesses, etc. The study of

SURGERY OF THE SPINAL CORD

is of more recent date. Few cases have been reported.

In the same Section DR. OSCAR J. CORKERY reported a case of

TREPHINING FOR CEREBRAL ABSCESS,

with the result of removing the pus and giving motion to a paralyzed arm and leg; but the patient eventually died.

DR. JOHN C. JAY then reported

A CASE OF ENTIRE EXSECTION OF THE ULNA, WITH RESECTION OF THE HUMERUS AND RADIUS,

in a woman forty-nine years of age. Complete anchylosis did not occur and the elbow remained movable to the extent of several inches, and thumb and two fingers could be used. The operation was fully justified by the excellent results.

SECTION ON PRACTICE OF MEDICINE.

WILLIAM B. CANFIELD, M.D., CHAIRMAN.

DR. CANFIELD took up the following subjects:

I. THE RELATION OF DUSTY OCCUPATIONS TO PULMONARY PHTHISIS.

He began by saying that the pulmonary diseases, caused by the different kinds of dust, had received a variety of names according to the kind of dust inhaled, but collectively they were all covered by the name "pneumonoconiocis." Ever since Koch's discovery of the tubercle bacillus, and the gradually improved classification of lung diseases, there seemed to be doubt whether these dust diseases were tuberculous or not. The dust inhaled by miners in badly ventilated mines gradually overcame the action of the ciliated epithelium, and penetrated to the alveoli of the lung, whence they found their way into the subepithelial layer, where, unless rendered harmless or devoured by the greedy phagocytes, they set up a fibroid condition of the lung. Most writers agree that the fibroid condition is a barrier to the growth and multiplication of the bacillus.

He then related the case of a miner who had a fibrosis of the lungs, and in whose sputa bacilli were always found at every examination, and yet this man improved and is now well. His conclusions from this case were:

1. Patient had no previous history of, or predisposition to, tuberculosis.
2. He contracted a disease with which tuberculosis is supposed to be very rarely found.
3. He had tubercle bacilli in abundance in his sputa.
4. He is now entirely well.

II. THE PRESENT ASPECT OF THE QUESTION AS TO THE ETIOLOGY OF PNEUMONIA.

Pneumonia results from something more than "catching cold." Sailors lead an exposed life and rarely have

it. A large number of investigators have been looking for the specific organism. Talamon did some excellent work. Friedländer's pneumonococcus was accepted for a time, but the investigations of Fränkel and Weichselbaum have shown Friedländer's organism to be only an accidental accompaniment of pneumonia. Good work has been done by Gamaléia, Sternberg, Lipari, and others. He referred to the theory of phagocytosis in connection with this subject, and related his own experience in the bacteriological study of this organism. He then took up

III. THE MORE RECENT TREATMENT OF PULMONARY PHTHISIS,

and spoke of the failure of Bergeon's method. Treatment has been carried out by:

1. Internal administration of drugs or medicines.
2. Intra-pulmonary injections.
3. Inhalations.
4. Climate. And cures occasionally occurred
5. Spontaneously.

1. The principal remedies recommended of late were creasote, tannin, calomel, and morrhuol. He had used creasote with some success.

2. Intra-pulmonary injections had been discarded.

3. Inhalations had no lasting influence on the lung-tissue; creasote, hydrofluoric acid, and hot air had all been used. Weigert claims to get some good effects from the latter.

4. Climate, in early cases well selected, is the best treatment. Many observers, particularly foreigners, gauge the improvement or the reverse by the diminution or increase of bacilli found. This hardly seemed to be the proper test. Patients often do well when their sputum is laden with bacilli. Cures may result

5. Spontaneously, as Vibert has shown in his statistics, gathered from the Paris Morgue. In one hundred and thirty-one persons between twenty and fifty-five years of age, all of whom died violent or sudden deaths, in seventeen, or sixty-eight per cent., evidences of cured consumption were found in the lungs. These facts should be borne in mind by those reporting cures from the use of new remedies.

DISCUSSION.

Dr. W. S. Forwood, of Darlington, Md., said that the "flint disease," as it was called in Harford County, was very common and very fatal with the workmen in the quarries. The men all have this disease, which begins very insidiously as a slight cough and grows worse. It ends like consumption, but the beginning is very different. In reply to Drs. Randolph Winslow and A. K. Bond, he said that no one escaped the disease after working in the quarries, and all were permanently injured, even if they gave up the occupation in a year.

Dr. J. T. Wrightson, of Newark, N. J., said that lung disease was very common among the hat-makers of his city, but he attributed it not so much to the dust as to drinking.

THIRD DAY, THURSDAY, APRIL 25TH.

SECTION ON OBSTETRICS AND GYNECOLOGY.

T. A. Ashby, M.D., Chairman.

The Chairman remarked first on the growing tendency to abandon empirical methods, and to employ more rational views of pathology and treatment. The study of abdominal surgery claims attention; exploratory laparotomy is the only correct means to use in some cases; laparotomy for pelvic abscess is a subject gradually gaining upon the professional mind. Primary laparotomy in tubal pregnancy has been brought into conspicuous prominence of late, but the greatest interest had been aroused in the use of

ELECTRICITY IN GYNECOLOGY.

He then discussed the various diseases for which electricity had been used, and then showed how much had been accomplished by it in a short time.

Dr. L. E. Neale then exhibited

A NEW OBSTETRICAL FORCEPS

which was a modification of Howard's modification of Tarnier's. He called it "Neale's Forceps." He claims superiority on the ground that it is all hard metal and can be made thoroughly aseptic, has Simpson lock, blades are narrowing, preventing rupture of perineum.

DISCUSSION.

Dr. P. C. Williams praised it very highly. He liked Tarnier's handle. In using it as ordinary forceps, he thought there was not force enough at the handle to manage it. It has many advantages which made it a superior instrument to the others.

SECTION ON MATERIA MEDICA AND CHEMISTRY.

T. Barton Brune, M.D., Chairman.

Dr. Brune read a paper on

SUGAR TESTING WITH SPECIAL REFERENCE TO ALCAPTONURIA,

in which he reviewed the various substances giving a sugar reaction, and the danger of trusting too much to one test alone.

In the same Section Dr. W. B. Platt took up the subject of

SURGICAL THERAPEUTICS,

in which he considered all curative, non-mechanical agencies employed in surgical cases, whether after accident, operation, or for surgical diseases. These he classified as anæsthetics, antisyphilitics, and antiseptics. In the first class he discussed protoxide of nitrogen, chloride of methyl, and cocaine. Under antisyphilitics were mentioned mercury by inunction, hypodermic injections, and gray oil. The antiseptics were carbolic acid, creolin, and iodoform.

Dr. Whitfield Winsey then read a paper on

HYPNOTICS AND ANTIPYRETICS.

In the former case he reviewed what is now known of sulfonal, and drew the following conclusions:

1. It is a true hypnotic.
2. It is easy of administration, being without taste or odor.
3. It is safe, prompt, efficient, with no objectionable after-effects.
4. No sulfonal habit is contracted.

Under antipyretics he went very thoroughly over the literature of antipyrin, antifebrin, and phenacetin.

Dr. H. Salzer read a very exhaustive paper on

LAVAGE,

and gave the indications for its use in adults and children, and his experience with it. In the

DISCUSSION

which followed, the remarks were confined to glycosuria and the sugar tests.

Dr. A. K. Bond thought the testing for sugar was not so simple a method as it appeared. He thought the phenylhydrazin chloride test was the most satisfactory, but agreed with Dr. Brune that no one test should be used alone.

Dr. George J. Preston said it was important to know whether the amount of sugar increased or decreased.

Dr. William B. Canfield thought no test was reliable. He had succeeded with other tests where the phenylhydrazin chloride test had failed. He thought the use of the microscope was an objection to this test, as probably two-thirds of the medical graduates of the United States did not know how to use the microscope.

Dr. I. C. Hemmeter was surprised that the saccharimeter had not been mentioned. Salkonsky and Leube proved that it showed the presence of one-tenth of one per cent.

Dr. T. B. Brune, in closing, said he regretted to bring such a long discussion before the Society. The phenylhydrazin chloride test had not been long enough before the medical public to judge of it yet. Some other substance, as carbohydrates, may reduce these crystals.

SECTION ON SANITARY SCIENCE.

Dr. W. C. Van Bibber read a report on the subject of

QUARANTINE,

in which he discussed the Maryland Health and Quarantine Establishment, and referred particularly to yellow fever.

Fourth Day, Friday, April 26th.

SECTION ON ANATOMY, PHYSIOLOGY, AND PATHOLOGY.

William H. Welch, M.D., Chairman.

The Chairman took for his subject

HYDROPHOBIA.

He said that although, since Pasteur's first publications on this subject, it has received the widest ventilation in medical journals, no apology is needed for a fresh critical review, so rapid are the additions to our knowledge, and to such an extent does the estimation of the value of much of Pasteur's work depend upon results which can be determined only by the lapse of time. Although Pasteur's preventive inoculations against hydrophobia constitute the central point about which controversy has waged, it is not to be forgotten that Pasteur's discoveries, and the investigations aroused by them, have shed much light in many directions upon one of the most mysterious and fatal diseases. We are better able now than ever before to estimate the value of the recent studies of rabies, and to consider the efficacy of the Pasteurian inoculations against hydrophobia.

Dr. Welch reported the results of post-mortem examinations which he had made in three cases of hydrophobia in human beings. In one case he had made serial sections of the medulla oblongata and pons from the second cervical nerve upward. The lesions in this situation were small hemorrhages, accumulations of leucocytes in large numbers in the perivascular lymph-spaces and in scattered foci in the neuroglia, and thrombi composed of blood-plates and of leucocytes in small blood-vessels. These lesions were for the most part microscopical, and their extent and distribution could be determined only by the examination of a large number of sections from different parts. The lesions were especially well marked in and near the nuclei of origin of the spinal accessory, pneumogastric, and glosso-pharyngeal nerves, and in the motor nucleus of the trigeminus. Cases have been reported in which even more extensive lesions than these have been found, their severity depending apparently in large measure upon the duration of the disease. While it cannot be claimed that these lesions are peculiar to hydrophobia, or by themselves suffice for its anatomical diagnosis, it is incorrect to suppose that hydrophobia is a disease without demonstrable anatomical lesions which bear a manifest relation to the symptoms of the affection.

Far more important than the additions to our knowledge of the pathological anatomy of rabies following Pasteur's discoveries, are the contributions to a better comprehension of the causation of the disease. Before Pasteur's publications on hydrophobia, dating from 1881, about all that we knew of the virus of rabies was that it is contained in the salivary glands and their secretion, and that infection often follows the bites of rabid animals. We now possess valuable information concerning the properties of the rabid virus, its distribution in the infected body, the manner of its transmission, the singular differences in its action according to the seat of its inoculation, and the means for producing immunity against its invasion.

Although there is no reason to doubt that the infectious agent in the virus of rabies is a micro-organism, no actual demonstration of this organism has yet been made. From material obtained from a series of rabbits which were inoculated at the pathological laboratory of the Johns Hopkins University, with hydrophobic virus obtained from the medulla oblongata of a man dead of the disease, and which served to confirm the statements of Pasteur as to the behavior of these animals when inoculated with the rabid virus, efforts were made to demonstrate, both in the tissues and by means of cultures, some specific micro-organism, but with entirely negative results. While we are not acquainted with the specific organism causing hydrophobia, we know many of its properties.

The virus of rabies is destroyed by comparatively low temperatures, exposure for one hour to a temperature of 50° C., sufficing for this purpose. It is killed in a short time by drying—certainly within four days when exposed in thin layers capable of rapid desiccation. It is destroyed by exposure to the direct rays of the sun, even when surrounded by conditions preventing much elevation of temperature. According to Babes, the virus is more resistant to the action of corrosive sublimate and of carbolic acid than most micro-organisms; but it usually loses its infectious properties after exposure for three hours to the action of 0.1 per cent. sublimate, or one per cent. carbolic acid solution. Galtier has pointed out the important fact that the virus of rabies may be demonstrated after forty-four days, and perhaps longer, in the cadavers of buried animals. A practical means of preserving the virus is to place the brain or cord of the infected animal in pure glycerine which may be diluted with water, and should be occasionally changed.

It has been ascertained that the occurrence of infection with rabies depends largely upon the part of the body and the character of the tissues into which the virus is inoculated. The disease always develops after inoculation of the virus into the brain, or upon its surface, or into the eye, the period of incubation being shorter and more definite after subdural inoculations. Inoculation into the substance of nerve-trunks appears to be equally successful in rabbits, but somewhat less certain in dogs, although even with the latter, inoculation into the pneumogastric nerves does not fail. Intra-venous injections do not produce the disease in ruminants, unless very large quantities are used, and may fail in rabbits, and especially in dogs. Especial importance attaches to the behavior of subcutaneous injections of the virus of rabies. Dogs often resist infection from the injection of considerable quantities of even the most intense virus into the subcutaneous tissue. Ferran's superintensive method of producing immunity in human beings is to inject at once the strong virus into the subcutaneous tissue, and this has been done in over two hundred cases without injury. If the injection be made into muscular tissue, infection is more likely to follow. Di Vestea and Lagari have shown that, while simple subcutaneous injections are often unsuccessful in producing rabies, the application of the virus to the divided ends of nerve-filaments in a cutaneous wound is generally efficacious in causing the disease. Although deep and severe bites of rabid animals are the most dangerous, hydrophobia may result simply from a mad dog licking a scratch in the skin.

One of the most important discoveries of Pasteur is the demonstration of the fact that, in animals or human beings which have died of hydrophobia, the virus is contained most abundantly in the central nervous system, and especially in the medulla oblongata. It is found constantly also in the salivary and lachrymal glands, sometimes in the pancreas, but it is usually absent from the blood, kidneys, spleen, and liver. Only exceptionally is it present in the

mammary glands and the milk. It is very rarely transmitted to the fœtus through the placenta.

There has been considerable discussion as to the manner in which the virus is conveyed from the seat of inoculation to the central nervous system. The evidence points to the transmission of the virus along the nerves, in fact it is claimed by Helman and others that the virus is capable of multiplication only in nervous substance. Roux and others have found the virus present in the nerves of a bitten extremity when it has been absent in corresponding nerves of the opposite side. By killing animals at the proper period it has been ascertained that after inoculation in the tail or posterior extremities the virus makes its appearance in the posterior part of the spinal cord sooner than in the medulla oblongata, while the reverse holds true when the inoculation is made in the head or anterior part of the body. These observations, taken together with the inefficacy of intra-venous injections and the absence of the virus from the blood, lead to the conclusion that the virus passes along the nerve-trunks, although we have no information as to how this is accomplished.

It is a significant fact, which should be remembered in judging the results of Pasteur's treatment, that there is a period of so-called latent development of the virus in the central nervous system. In rabbits inoculated with the strongest virus (virus fixe) the period of incubation is six days, but as early as the fourth day the virus has been found in the medulla oblongata. Doubtless, therefore, in human beings the virus is present for a longer or shorter period in the central nervous system before any characteristic symptoms of rabies appear. Careful observation has shown that in rabbits this period is not really a latent one, but is accompanied by elevation of temperature, increased frequency of respiration, slowing of the pulse-rate and loss of weight.

Dr. Welch said that there can no longer be any question that it is possible to render animals immune against rabies, both before and after inoculations which would otherwise cause the disease. The independent and careful experiments of Ernst in this country are free from all partisan bias and have amply confirmed the statements of Pasteur on this point. The methods employed by Pasteur for protective inoculation against hydrophobia have been so often and so fully described in medical and other journals that Dr. Welch did not consider it necessary to repeat the description on this occasion. Those inoculations are the most effective in preventing the disease which are undertaken soon after the reception of the poison with a large quantity of virus, and with the speedy employment of material containing the strongest virus (virus fixe). Animals may be rendered immune by single injections into the blood or the subcutaneous tissue of a large quantity of strong virus, whereas dogs which are bitten by mad dogs and which do not develop the disease, as often happens, are not left immune. Dogs which have once been rendered immune against rabies may preserve this immunity for at least two years, and doubtless for a longer period.

Pasteur attributes the immunity to the action of some substance which he calls "matière vaccinale" contained in the virulent material, but not identical with the micro-organism causing rabies. That immunity against infectious diseases may be secured by the injection of chemical substances produced by the growth of specific bacteria was first demonstrated by Salmon and Smith in the case of hog cholera, and has been subsequently demonstrated by Roux and Chamberland for malignant œdema, and by Woodridge for anthrax. It has not yet been found possible to prove conclusively the correctness of Pasteur's supposition in the case of rabies, but there is much which speaks in its favor.

Encouraged by the result of his experiments upon animals, Pasteur, in July, 1885, first applied to a human being his method of preventing hydrophobia by successive inoculations of the virus contained in the rabbit's medulla subjected to drying for different periods. During the years 1886, 1887, and the first half of 1888, there have been treated, under Pasteur's supervision, either by the simple or the intensive method of inoculation, 5,374 persons who have been bitten by animals either proven or suspected to be rabid. The mortality from hydrophobia, including even the cases which developed within a day after the cessation of treatment, was, in 1886, 1.34 per cent.; in 1887, 1.12 per cent.; in 1888, 0.77 per cent. If the fatal cases which developed within a fortnight after the end of treatment, and in which there is reason to believe that the inception of treatment was too late, be excluded, the mortality for 1886 falls to 0.93 per cent.; for 1887, to 0.67 per cent.; and for 1888, to 0.55 per cent.

Dr. Welch considered the various objections which have been made to Pasteur's methods, and to the value of his statistics. Some of these objections are of a purely hypothetical nature. Much force has been attached to Von Frisch's experiments which seemed to some to invalidate the scientific basis of Pasteur's method of treatment. Von Frisch claimed that it is impossible to render animals immune after the reception of the virus of rabies in a manner certain to produce the disease. In opposition to Von Frisch it has been demonstrated by Pasteur and others that in a large proportion of cases the development of rabies may be prevented in dogs which have been inoculated beneath the dura mater with the strongest virus. The treatment, however, must not be deferred under these circumstances later than the second day, and must be by the intensive vaccinations. Bardach succeeded in this way in saving 60 per cent. of the dogs inoculated beneath the dura mater. This test is evidently the most severe one to which Pasteur's preventive treatment can be subjected, one far more severe than is required to meet the ordinary channels of infection with rabies. It must be admitted, therefore, that Pasteur's treatment rests upon a satisfactory experimental basis.

The criticisms raised against drawing favorable conclusions from the large mass of statistics published by Pasteur have been many, but the most important are that we are ignorant of the mortality following the bites of rabid animals, and that there are included in Pasteur's statistics an indeterminate number of persons bitten by animals not rabid. As regards the first point there are various careful collections of statistics which show an average mortality of about 15 per cent. (Leblanc, Dujardin-Beaumetz, Horsley). All admit that bites by rabid animals on the head and face furnish a much higher death rate than this, it being given as 88 per cent. by Brouardel. To meet the second criticism Pasteur's statistics, which are published monthly, are arranged in tables which embrace: (A) Persons bitten by animals proven experimentally to be rabid; (B) cases in which the existence of rabies is certified by a veterinarian; (C) cases in which there is reason to suspect rabies in the animal. Pasteur's statistics for class A—that is for persons bitten by animals proven experimentally to be rabid—for the years 1886, 1887, and the first half of 1888 yield a mortality from rabies of 1.36 per cent., or if those who died within a fortnight after treatment be excluded, of 1.09 per cent.

Dr. Welch collected from Pasteur's reports for the year 1887, and the first half of 1888, those bitten on the head and face proven experimentally to be rabid. There were 59 cases with 4 deaths from rabies during treatment, and 2 following treatment. Of the latter one was seized three days after the cessation of treatment, and it is reasonable to suppose that in this case the treatment was begun too late. If this case and those dying during treatment be excluded there remain 54 cases with 1 death, a mortality of 1.85 per cent.

In view of the universally conceded high death rate following bites on the head and face by rabid animals, this result leaves no room for doubt as to the efficacy of Pasteur's treatment, although it is not unfailing.

It is a sufficient answer to the assertion which has been

made that Pasteur's intensive inoculations are dangerous, in that they may actually produce the disease, that the mortality from rabies is strikingly smaller after the application of the intensive method than after the simple treatment.

Dr. F. T. Miles then read a paper entitled

A CASE OF DILATATION OF THE STOMACH, DEPENDENT UPON CONTRACTION OF THE PYLORUS.

in which tetany of a typical character occurred, speedily ending in death. He could find nothing in the vomited matter to account for it.

Dr. J. W. Chambers submitted a paper on

CYSTIC TUMOR OF THE LOWER JAW,

which was read by title.

Dr. George J. Preston reported a case of

TUMOR OF THE CEREBELLUM

pressing on the middle lobe.

In the

DISCUSSION

which followed,

Dr. J. D. Blake, referring to Dr. Welch's paper, asked how the poison could be transmitted by the nerves alone. If injection into the blood does not kill, but makes the animal proof against future attacks, why not inject the substance directly into the blood of man to prevent hydrophobia?

Dr. W. C. Van Bibber said if the temperature stated would kill the organism of rabies, this should give a valuable idea on the treatment.

Dr. William H. Welch remarked in conclusion, that many facts about rabies are known which could not be explained. It was not understood how the virus was transmitted along the nerves, but the fact remains, and still further, this did not seem to disturb the function of the nerve. It might extend along the lymph-vessels of the nerves; we know little of the composition of the lymph. He did not mean to be understood as saying that the virus did not extend through the blood, lymphatics, etc., but that we have no evidence of this. In reply to Dr. Van Bibber, he said that the method of cauterization is a good one, but it does not prevent rabies. The virus must penetrate into the nerve to be transmitted by it, and the chance of piercing a nerve in the skin by puncture is very small.

SECTION ON PSYCHOLOGY AND MEDICAL JURISPRUDENCE.

Richard Gundry, M.D., Chairman.

The Chairman read a paper on

THE RELATION OF THE PHYSICIAN TO THE INSANE,

and spoke particularly of the frequency of monomania, and of the difficulties of recognizing true insanity by the unskilled; as a person may be entirely sane on many subjects, and insane only on a few. A person totally insane has no recollection of a deed committed, while a person partly insane may remember the past partly.

SECTION ON MICROSCOPY, MICRO-CHEMISTRY, AND SPECIAL ANALYSIS.

Christopher Johnston, Sr., M.D., Chairman.

The Chairman read a report on

THE APPLICATION OF SPECTROSCOPY TO THE STUDY OF THE BLOOD, AND THE AMERICAN OBJECTIVE AS COMPARED WITH THE GERMAN.

SECTION ON OPHTHALMOLOGY, OTOLOGY, AND LARYNGOLOGY.

Dr. H. C. McSherry read a paper on

CURABILITY OF LARYNGEAL PHTHISIS;

and Dr. A. Friedenwald one on

DISTURBED EQUILIBRIUM OF THE MUSCLES OF THE EYE IN THE CAUSATION OF NERVOUS DISEASES.

Volunteer papers were then read by Dr. S. J. Fort, on

APHASIA DUE TO SHOCK OF SEVERE CONSECUTIVE EPILEPTIC SPASMS;

by Dr. John C. Hemmeter, on

RECENT INVESTIGATIONS ON THE PHYSIOLOGICAL ACTIVITY OF ALCOHOL,

which was the result of three years of carefully conducted work in the biological laboratory of Johns Hopkins University; by Dr. A. K. Bond, on

ANEURISM OF THE ABDOMINAL AORTA BURSTING INTO THE PLEURAL CAVITY;

and by Dr. George H. Rohé, on

A PAINLESS AND EFFICIENT METHOD OF EXTIRPATING VASCULAR AND PIGMENTED NÆVI,

with exhibition of photographs.

OFFICERS ELECTED.

The following officers were elected for 1889–90:

President—Dr. A. Friedenwald; *Vice Presidents*—Drs. T. A. Ashby and Charles G. W. Macgill; *Recording Secretary*—Dr. G. Lane Taneyhill; *Assistant Secretary*—Dr. Robert T. Wilson; *Corresponding Secretary*—Dr. Joseph T. Smith; *Reporting Secretary*—Dr. William B. Canfield; *Treasurer*—Dr. W. F. A. Kemp.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

AN INTERESTING CASE OF ANEURISM—STEAM-JETS IN COTTON-FACTORIES AS A CAUSE OF DISEASE—TWO MEDICAL VETERANS—A DISTINGUISHED PARISH DOCTOR—THE RATE OF INCREASE OF THE PROFESSION—THE NEW LUNACY BILL—LATERAL CURVATURE OF THE SPINE, ITS CAUSATION AND PATHOLOGY—ABDOMINAL NEPHRECTOMY—SYPHILITIC FEVER NINE YEARS AFTER INFECTION—A PENNY-A-WEEK COLLECTION AMONG WORKMEN FOR THE BENEFIT OF HOSPITALS—A ROYAL COMMISSION ON VACCINATION.

London, April 9, 1889.

At the last meeting of the Pathological Society Dr. Mott read a paper in which he detailed the history of a case of some interest. The patient was a boy aged thirteen who was admitted into Charing Cross Hospital for well-marked aortic disease. There was some enlargement of the liver, pain and tenderness over the spleen, and the urine contained a trace of albumen. While in hospital the boy had frequent attacks of pyrexia, the temperature rising to 102° and 103° F., and the case was diagnosed as one of infective endocarditis, with extensive vegetations of the aortic valves. Severe pain occurred suddenly one day in the right hand, which was also numbed. No pulse could be felt in the ulnar artery at the wrist, and a little later the radial pulse also disappeared. Embolism of the ulnar and brachial arteries was diagnosed. No pulsating tumor ensued. The patient died three months later, and at the necropsy the heart was found enlarged, its tissue undergoing fatty degeneration, and there was extensive disease of the aortic valves, the cusps being covered with large calcareous vegetations. Similar vegetations (but smaller and more recent) were present on the anterior cusp of the mitral valve and the adjacent endocardium. There were many old infarcts in the spleen and left kidney. There was an aneurism of the ulnar artery just beyond the interosseous branch, and an aneurismal dilatation of the brachial artery at the lower border of the tendon of the teres major. Microscopical examination showed that the inner coat of the vessel was destroyed at the seat of the aneurism, and the middle and external

coats were separated by leucocytes. Dr. Mott remarked that the case was of interest as affording an undoubted example of aneurism following embolism. It was one of calcified aortic valves like that described by Ponfick, but it was also probably infective—hence the ulceration and the softening of the vessel-wall, and the production of aneurism. There was a striking similarity between the condition of the vessel-walls in this case and that of a case of ulceration and secondary hæmorrhage of the popliteal artery after ligature, the wound having become septic.

Among the recognized causes of pulmonary disease one of the most important is the inhalation of dust of various kinds, and the extensive mortality in certain occupations has been conclusively proved to be due to this cause. We now learn, on the authority of Dr. Arlidge, in his recent "Milroy Lectures," at the College of Physicians, that another danger has in recent years been added to those affecting one class of workers in dusty occupations, viz., operatives in cotton factories. To produce some qualities of fabric now in considerable demand for exportation, a certain degree of moisture is necessary, and to supply this it has become the practice to inject jets of steam into the weaving sheds. Not only the materials in process of manufacture, however, but the weavers themselves are covered with moisture from the steam thus introduced, and as a consequence, impaired digestion, vertigo, rheumatism, and respiratory disorders are unduly prevalent among them. The matter is one urgently needing legislative interference.

Two medical veterans have recently entered into rest, viz.: Dr. C. J. B. Williams, and Dr. Joseph Rogers. Their life-work lay in very different directions. Dr. Williams had sufficient advantages of fortune to enable him to commence practice at the West End as a consulting physician. He had previously, after graduation at Edinburgh, studied a year in Paris, where he was a pupil of Laennec. On returning to this country, therefore, he became one of the pioneers of auscultation, among his contemporaries and fellow-workers in the same field being Archibald Billing, Thomas Davies, and many others long since deceased. Dr. Williams was one of the founders of the Brompton Consumption Hospital, to which institution his son (Dr. Theodore Williams) is now senior physician. He enjoyed for many years a large and lucrative practice in diseases of the chest.

From a consulting physician to a parish doctor is rather a long stride, but the late Dr. Joseph Rogers, probably, did as useful work in his day, in the latter capacity, as was done by Dr. Williams in his more exalted sphere. Dr. Rogers spent almost the whole of his professional life in the Poor-law Service, and was recently President of the Poor-law Medical Officers' Association. He was during many years indefatigable in his efforts to improve the position of medical officers in the Poor-law Service, and it is to his exertions that many of the most useful reforms are due.

A survey of the figures contained in the new volume of the *Medical Register* is calculated to "give us pause." It appears that no fewer than 1,184 new names were registered last year, while only 511 medical men died. The net gain to the ranks of the profession was, therefore, 673. If we go back to the statistics of former years, we find from them that the same rate of increase has been going on for years. What is to become of them all, and from whence are sufficient patients to be obtained to support this ever-increasing army of practitioners?

The New Lunacy Bill still lags in Parliament. To any medical mind one of the most objectionable clauses is that which allows a patient to be interviewed by a magistrate, who may then veto his admission to an asylum without assigning any reason whatever! The only way in which this clause could be rendered unobjectionable would be by delegating the duty to medical magistrates, who should, of course, be debarred from practising otherwise, but receive a salary for their services.

LONDON, April 15, 1889.

The "Causation and Pathology of the More Common Forms of Lateral Spinal Curvature" constituted the subject of a somewhat elaborate paper by Mr. Arbuthnot Lane, read before the Medical and Chirurgical Society at their last meeting. The author endeavored to show that most cases of lateral curvature were the result (1) of the fixation and (2) of the exaggeration of a normal and physiological attitude. In the case of the labor curves, the attitude, which was fixed and exaggerated, was one of activity; in scoliosis it was one of rest. After discussing the structure of the vertebral column, and the influences which determined the form of its curves in a vertical antero-posterior plane, Mr. Lane proceeded to consider the manner in which the characters of these curves might be modified in the same plane by labor, symmetrical postures of rest, and by disease of the column itself. In symmetrical flexion of the column, though the fibro-cartilages were rendered more or less wedge-shaped (the thicker part being directed backward), yet the whole of the fibro-cartilaginous disk was compressed, owing to the resistance offered by the spinous processes and their connecting ligaments. Should flexion be habitually maintained beyond the physiological or recoverable period, the whole of the fibro-cartilage was diminished in depth, though this was much more marked in front of than behind the transverse axis of rotation. The column was no longer able to resume its normal curves. Supposing the column to be vertical, to consist only of vertebræ and intervening disks of cartilage unconnected with the other portions of the body, and situated upon a horizontally placed sacral facet; if the upper end of the column were made to remain in a vertical antero-posterior plane, any lateral inclination of the sacral facet must be followed by a rotation of each body around an antero-posterior axis so as to form a long single lateral curve. The segment of fibro-cartilage corresponding to the concavity of the curve would be compressed, while that corresponding to its convexity would be elongated, since in the formation of this lateral curve there was no such resistance offered to its development as was afforded in flexion by the spinous processes and connecting ligaments. In such a hypothetical condition the line formed by the apices of the spinous processes would deviate from the middle line to the same extent as that formed by the centres of the bodies of the vertebræ. Should that easy erect posture be assumed in which almost the whole of the weight of the body was supported upon one leg, the sacral facet was inclined considerably to one side, so that we had present both a flexion of the column produced by a rotation of the bodies of the vertebræ around a transverse axis, and a flexion produced by their rotation around an antero-posterior axis. This resulted practically in the rotation of each body around an axis in a horizontal plane which occupied a position between these, its direction being obliquely forward and outward. As a consequence of this, the antero-lateral segment of fibro-cartilage corresponding to the concavities of the two curves was exposed to much pressure, while the opposite segment was placed on the stretch. This condition of the fibro-cartilage became permanent when the attitude in question was too prolonged. Later still, as the deformity became exaggerated, the bones underwent corresponding changes in form. In this case, owing to the oblique direction of the axis of rotation, the spinous processes formed by no means such a marked curve as did the bodies of the vertebræ. The same combination of transverse and antero-posterior rotation was frequently present in the sedentary attitudes of rest.

Mr. William Adams remarked that Mr. Lane had laid too much stress on the mechanical causes of the curvature. The predisposing causes must not be forgotten. He was inclined to divide cases of scoliosis into three classes: 1, Those occurring in children under twelve years of age, which were mostly due to the strumous and rachitic diatheses; 2, those in children between twelve and sixteen,

which were due to hereditary, constitutional, or local causes; 3, cases in children over sixteen, in which local causes predominated. Other theories, such as that of muscular contraction by Guérin and of rotation by Dodd, were still open to discussion. The spine never curved laterally, but the bodies of the vertebræ rotated horizontally. Why did the bodies of the vertebræ rotate? He believed the mechanical theory was the correct one. The oblique articulating processes allowed of lateral movement in the cervical region, but of very little in the dorsal region, and of practically none in the lumbar portion of the spine. He accepted Mr. Lane's account of the changes which occurred in the intervertebral disks, and claimed that the articulating processes accommodated themselves to the changes; the result being that the bony structures had to undergo changes corresponding with those of the cartilages.

Mr. Barwell observed that the term "rotation" had been hitherto used to denote that motion by which the anterior faces of the bodies of the vertebræ looked toward the convexity of the curve, while the spines looked toward the concavity; its use for any other conditions was to be avoided. In many cases in young children a simple curve of the whole column was met with. The rotation of the sacrum or obliquity of the pelvis did produce to some degree the loin curve, but this was compensated for by the opposite direction of the facet on the inferior surface of the last lumbar vertebræ. The normal position of the lumbar spine in the sitting posture was a curve with the concavity forward. Mr. Lane had attempted to account for all lateral curves by the action of the balance, but this could not explain those curves which were primarily dorsal, and which remained confined to the dorsal region till a comparatively late period. He was not certain that confirmed lateral curvature was incurable, but thought much improvement could be effected if a pertinent apparatus were applied and muscular action encouraged.

Mr. Lane, in reply, said he had been able to satisfy himself that these curves were simply the fixation and exaggeration of normal attitudes. In children these were the attitudes of rest (resting curves), in adults those of activity (labor curves.)

Mr. Knowsley Thornton then read a paper on "Abdominal Nephrectomy," in which he gave an account of twenty-five cases. Only five of these had terminated fatally, but two of the deaths were not properly to be counted against abdominal nephrectomy, one being due to the perforation of the right pleura by a malignant tumor, and the other to hemiplegia, which was brought on by the anæsthesia rather than by the operation. Mr. Thornton thought nephrectomy was superior to nephrotomy and drainage for the cure of hydronephrosis. He condemned incision of a suppurating kidney as a preliminary to nephrectomy, but strongly advocated the removal of the kidney without any puncture during operation whenever the size permitted. Langenbuch's incision was the best. Mr. Thornton said his practice of pinning out the ureter had led to no trouble, and he considered it the chief factor in securing the success attained. He thought it would prove a measure of safety even in lumbar nephrectomy.

Mr. Clement Lucas said a great point was to ascertain that the other kidney was healthy, and, if the amount of urea secreted was less than half the normal quantity, the operation must necessarily be a very serious one. In kidneys with hydronephrosis he was sure nephrectomy was right and nephrotomy wrong; if the kidney refilled after one aspiration, it should be removed. He questioned the safety of removing suppurating kidneys through the peritoneum. The ureter had never given him the least trouble, and he had not once regretted dropping it back after simple ligature.

At a recent meeting of the Medical Society of London Dr. Sidney Phillips read a paper in which he described a case of syphilitic fever with somewhat unusual features. The fever occurred nine years after infection, lasted eight months, and resembled that of tertian ague. The attacks recurred every day at first, and then every other day. They were accompanied by shivering and sweating. Ten days after the admission of the patient to hospital quinine was administered to her in two-grain doses three times a day, and then five grains were given before the expected pyrexial attack. This checked the fever for a time, but afterward failed to do so, although the dose was increased. Iodide of potassium and mercury, however, when given, not only reduced the temperature, but relieved the headache and vomiting which had been present. The question was raised whether the pyrexia was associated with a local syphilitic lesion, but no localizing evidence could be obtained. Erythema nodosum was present, and, apart from syphilis, it was rare to find this accompanied by fever. Similar cases of syphilitic fever had been described by John Hunter and Fournier, but none so late as the ninth year after infection.

It is proposed to supplement the collections made on "Hospital Sunday" and "Hospital Saturday" by instituting a "penny-a-week" collection in workshops. It is estimated that a sum equal to half a million dollars may thus be raised.

The Government has consented to appoint a Royal Commission to inquire into the working of the Vaccination Acts.

WANTS TO KNOW IF CHRONIC NASO-PHARYNGEAL CATARRH CAN BE CURED.

To the Editor of The Medical Record.

Sir: We see occasionally, in fact frequently, in the medical journals the mention of one or another drug or remedy as useful in chronic nasal, naso-pharyngeal, and pharyngeal catarrh.

Now, can any one suggest an effective treatment for a class of catarrhs of which I shall speak? I have turned to the pages of treatises on diseases of the nose and pharynx, and read up in the medical journals on the subject till I'm aweary, and yet I find no comfort. I do not refer to "catarrh" in the "phlegmatic" or "bilious" type of patient; anybody can cure that, or come as near curing it as the climate will permit. But I allude to a class of cases that forms a very large part of the number seen by every physician, *i.e.*, catarrh in subjects of the "nervous" and "sanguino-nervous" temperaments.

Stimulating treatment, so far as my experience goes, is worse than no treatment, no matter what may be the character of the astringent used. Sedative treatment is delusive at the beginning, but soon displays its true value, for the last state of that case is worse than the first. Persons suffering from this kind of catarrh rarely ever hawk out the thick, opaque mucus, but eject a thin, glairy, clear mucus from much swollen mucous membranes, and suffer fully as much discomfort from the necessity of frequent expectoration and the stuffy feeling as do those who have the other form of the disease.

I am a sufferer myself from this form of catarrh, and my personal experience for years, with self-treatment and treatment at the hands of others, has borne out the views stated above in regard to treatment.

I am aware that communications of this character appear more in place in some of the numerous "Physicians' Own Review" monthlies; but if others have the same experience that I do, why should not the matter appear in a journal of the character of The Record? If my experience is unusual, there must still be a number who have had ill-success in the same line, and a little honest airing of the subject in your columns by some experienced rhino-pharyngo-laryngologist might help some of us to gain a better knowledge as to what can and what cannot be done.

It were an end to be desired to gain a position where we could, without fear and trembling, view the approach of one of these fair-haired, "nervous" victims of naso-pharyngeal catarrh, even as we now look on one of the dark, phlegmatic class of sufferers from the same disease,

as the prospective field of conflict between disease and "scientific" medicine, in which the latter will surely gain a glorious victory.

Can you come over into Macedonia and help us, or has the work not prospered enough yet in the coasts of Asia to send out help to any country? G. P. H.

A PLEA FOR A MORE ASEPTIC SURGICAL POCKET-CASE.

To the Editor of The Medical Record.

SIR: The pocket-case of instruments is, of course, indispensable, but often the results of good surgery are defeated because it is dirty. Its instruments are called out in emergencies when there is rarely time to cleanse or disinfect them before using. Moreover, being generally employed for minor surgery, not so much thought is bestowed upon the necessity for their cleanliness as is given to instruments used for large and definitely timed operations. But their very folding shape and the nature of their employment especially adapts them to becoming foul, difficult to cleanse, and liable to convey sepsis. The clasp bistoury, after use, is too often simply dipped in water and hurriedly wiped, and even after it has been completely bathed in pus, which too often is never properly cleansed from the *interior* of its mischievous handle. In the hurry of selecting a needle from a needle-book, or piece of leather, how often is a bloody finger-mark left behind and several needles inevitably soiled. How often do we see silk carried in the instrument-case, and how often this is dirty. The very make-up and upholstery of the common case is a source of danger. Made of red or black leather, a soiled finger-touch is rarely visible or washed away. Lined with velvet or with silk, it can never be suitably cleansed. The insertion of an aseptic instrument into one of its soiled pockets will surely infect it and render surgical work with it in the future fraught with danger.

The pocket-case in common use has not kept pace with the rules and the requirements of modern surgery. Its clasping instruments—difficult with the greatest care to cleanse—should be replaced by those of a more aseptic pattern. Its upholstery with silk or plush should be abolished. There should be a means of carrying catgut in it properly prepared and guarded against pollution. More care should be bestowed upon the disinfection of the pocket-case, for although the instruments be placed in antiseptic solutions before and after use, yet they will always be dangerous if carried in a filthy case. As it exists to-day, it is a source of danger and too often a nuisance.

John Hammond Bradshaw, M.D.

Orange, N. J.

ANOTHER SIGN OF INTESTINAL PERFORATION.

To the Editor of The Medical Record.

SIR: The ingenious device of Dr. Senn has directed the attention of the profession very strongly to the possibility of making a diagnosis of intestinal perforation, in perforating wounds of the abdomen, during the life of the patient. I wish merely to record a post-mortem sign, which in an experience of a number of years in the mortuary of the Cincinnati Hospital has invariably been found, and of which I have seen no mention in the books. The change is found in the liver especially, and, to a less degree, in the spleen, and consists in a peculiar grayish-blue discoloration of the whole or nearly the whole surface of these organs. The alteration in color is quite characteristic, and is found in only one other condition, viz., chronic malarial pigmentation. From this latter condition the discoloration of intestinal perforation is readily differentiated by the fact that it is always quite superficial, rarely affecting the gland substance to a depth of more than one-sixty-fourth of an inch below the capsule; while in the case of malarial pigmentation the change is pretty uniformly disseminated throughout the entire gland. An observation of upward of thirty cases of intestinal perforation due to penetrating wounds has pretty well established the constancy of its occurrence. The discoloration becomes somewhat deeper with the length of time that has elapsed since the receipt of the injury; yet it is well defined when death occurs within the first twelve hours. The cause of this change in color is probably to be sought in the action of the sulphuretted hydrogen on the hæmoglobin, which, with the stagnation of the circulation in the superficial layers, due to the accompanying peritonitis, leads to a precipitation of a dark pigment (the sulphide of iron?). In the malarial cachexia large, irregular, granular accumulations of pigment are found deposited between the individual cells; in the case of the penetrating wound there is a very faintly granular deposit, which it is not always possible to differentiate from the ordinary bile-pigment.

This sign cannot of course compare in importance with the hydrogen test; yet there are cases in which the latter may for one reason or another not be applicable, or fail. In such cases, if an exploratory laparotomy be determined upon, it can add but little to the dangers of the patient to extend the incision upward sufficiently to expose the free margin of the liver for inspection. Should the discoloration be found and the history be that of a penetrating wound of the abdomen, there is almost positive proof of perforation. (I have in six hundred post-mortems met with but two cases of malarial pigmentation so decided as to give the slaty color—and it would be a rare coincidence that would bring us a patient suffering from an old malarial cachexia and a recent perforating abdominal wound.)

With this sign present, it would then become incumbent upon the surgeon to seek for the opening in the bowel. It is well-known that the reparative efforts of nature quickly surround the perforation with adhesive lymph, which tends to glue to the injured part neighboring coils of the intestine; and such adhesions might otherwise obstruct the search for the point of escape of gas and fecal matter.

It is not with any view of attaching great clinical importance to this alteration that I send you these lines; but rather that the attention of pathologists may be called to the subject, and because there is, as suggested, a possibility, however remote, that it may at some time prove of service *in vivo*. The liver is the organ most affected, and the change is more readily recognized here because the normal color of the splenic capsule frequently gives us a shade of slate color.

Very respectfully, Joseph Eichberg, M.D.

P. S.—In answer to an objection that will probably be raised, that there is no clinical history of the observation of any such change during life, I will admit that this is true; yet, on two separate occasions when the autopsy was made two and one-half and three hours, respectively, after death, the discoloration was so pronounced and had penetrated the capsule to such a depth as to leave little doubt that it was an ante-mortem occurrence. I cannot say positively how soon the discoloration begins; but it has been found in cases where not more than twelve hours have elapsed from the infliction of the wound to the fatal termination.

A UNIQUE EXAMINATION FOR HOSPITAL APPOINTMENT.

To the Editor of The Medical Record.

SIR: It is customary for the management of the Bellevue Hospital to issue notice that on certain dates a committee will be in session for the examination of candidates who seek places upon the hospital staff. These announcements generally reach the students of the various medical colleges in the country. They turn eagerly to compete for

positions upon this hospital's staff, not only because of the standing of the Bellevue medical college connected with the hospital, the fame of individual members of its faculty, and their operations in the hospital, but because other and exceptional advantages are attendant upon such work. The notices, or announcements, must, therefore, always bring into competition a number of the ablest of the more recent graduates in medicine. Those who come—at least those who come from afar—naturally and reasonably look for an examination in keeping with the dignity of the institutions, and the importance and responsibility of the positions under competition.

On March 26th last, a number of such men presented themselves at the hospital at the hour appointed for examination for the Fourth Division. After standing corralled in the rotunda for half an hour, they were given seats in an adjoining room. Shortly after they were summoned to the rotunda corral again, and left standing to the end of the examination—nearly three hours. They were called in turn before a member of the examining committee, and afterward returned to the rotunda to await the call before the next examiner. Every man on returning mingled with his friends. It is needless to add that he brought word of the character of the examination. Early in the contest it became known that some of the examiners were plying repeatedly the same questions—a matter beyond cavil had the contestants been kept apart. Happy was the man, therefore, who had "friends gone before." Such an one possessed a double advantage—what his friends had to report, and what the text-book, which he immediately consulted, had to say on the subject. And thrice and four times happy was he who was invited upstairs—to consult the authorities!

There were two kinds of examiners on the committee, professors from the New York colleges, and practitioners pure and simple. The questions of the former were invariably *essential* and to the point; those of the latter were often non-essential "catch questions," and one examiner, pregnant with his own ideas, often overrode well-accredited authors. For examples: One applicant was asked what he would do in case of stone in the bladder. "Crush it, and wash out the bladder," he answered. But he was met by the rebuke, "Under no circumstances wash it out—let it alone." On venturing the opinion that a stone in the pelvis of the kidney might be removed by cutting, he was ordered never to cut into the pelvis of the kidney. By another man, atony of the bladder and congestive stricture were given as causes for retention of the urine. This was met with contempt galore—"What do *you* know about congestive stricture and atony of the bladder?" Still another man lost his rating because he neglected to mention that fish-bones in the rectum are the cause of *fistula in ano*.

The question of the derivation of nephrectomy (commensurate in importance with another profound interrogatory of a previous examination as to the number of ova in the segment of a tape-worm, commented on in THE MEDICAL RECORD in '86) cost another man his head. Misfortune overtook another who came from a distance, and consequently pleaded ignorance as to what the invaginated catheter might be. The judgment of men learned in medicine must be at one upon the foregoing examples. Otherwise the examination was marred as to its fairness by the failure of applicants to appreciate the idiosyncrasies of some of the examiners. The gentleman who presided over catch questions, and who stated before the examination that questions would be asked that nobody could answer, and afterward admitted that such had been asked and nonessential details exacted only "for the fun of it," might have made Sitting Bull envious with the many scalps at his belt. Still a third element, peculiarly unfair, was the omission of any examination whatever in Practice, Obstetrics, and Gynecology.

Such were some of the phases of the examination. Was it in keeping with what the announcement would lead one to expect? The candidates had been preparing themselves for years in hopes of filling important positions. They were for the most part mature men, educated and gently bred, many of them worn with long and exhausting study. Was it considerate or decent treatment to oblige them to stand for hours on the cold marble floor of a hospital rotunda, exposed to drafts and colds to which the ordinary boss would not subject his laboring men? By what sort of foresight did the examiner propound the same question to men in turn?—the first to be examined retiring to post his friend upon the subject. Could the man coming from a distant college, with no friend in the arena, hope to win? Is it any wonder that ten *fratres in urbe* out of twenty-three competitors stood perfect on a most difficult question? Is it a wonder that the first were last and the last first? that the patient waiter was no loser? that the rank of the last men went up with the rapidity of Jonah's gourd? Who is so idle as to suppose that, where four are to be chosen, a man would not post his friend, and innocently tell the questions asked and his answers thereto?

Again, can it be said that an examination is conducted with fairness when the competitor's answers, according to a standard text-book, are discredited because that individual examiner holds an adverse opinion? It is hardly known whether the adverse opinion is in print. And is a man, reputed to be erratic, impulsive, falling short of considerate courtesy, and easily prejudiced, the best person to hold an examiner's position and deal fairly?

Further, catch questions cannot give an examiner the best inkling of the applicant's knowledge. Is it fair or dignified to press an applicant with such "for the fun of it?"

Again, it goes without saying that an applicant should be carefully examined in those branches of which he makes the most use in the position he seeks to fill. Any place in Bellevue Hospital demands such examinations. It has been noted that practice, obstetrics, and gynecology were omitted. This omission worked injustice in the examination, in that men best qualified in the above-named branches fell short in the general average. They lacked the advantage they might have gained if the examinations had been carried out roundly and completely. And what can be said in defence of the omission of so important a subject as the practice of medicine?

It may be added, in consideration of the rewards of the contest, that the fact of a man's fitness to serve is, outside of the examination, never gone into. "What have you ever done to develop executive abilities? What qualifications have you to recommend you outside of your book learning?" is never asked.

Is an examination possessing the unique features of this one as it decently should be? Is it consistent with what an applicant had been led to expect? Is the medical fraternity of New York City cognizant of its scope? Is it what the people should expect and demand?

In the event of the appointment of a State Board of Medical Examiners, the question has been raised whether such a body shall be made up from the medical professors of the State or from practitioners. The question in all its fulness applies to boards of examiners for hospitals. A study of the details of the late Bellevue examination might give arguments upon one side. But why should not the hospital examinations for Bellevue possess in the future the merit of courtesy—and also fairness and thoroughness?

J. WARREN ACHORN, A.M., M.D.

BROOKLYN CITY HOSPITAL, May 1, 1889.

THE AFTER-TASTE OF THE SALICYLATES.—When salicylic acid or salicylate of soda is given in solution, the unpleasant after-taste often causes nausea and vomiting. This can frequently be averted, says the *Omaha Clinic*, by placing a small quantity of table-salt upon the tongue immediately before the administration of these preparations.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 5 to May 11, 1889.

AINSWORTH, F. C., Captain and Assistant Surgeon. By direction of the Acting Secretary of War, will proceed to Albany, N. Y., on business connected with the Medical Department. Par. 7, S. O. 105, A. G. O., May 7, 1889.

APPEL, D. M., Captain and Assistant Surgeon. Relieved from duty at Fort Sill, I. T., and ordered to Fort Bliss, Tex. Par. 25, S. O. 104, A. G. O., Washington, May 6, 1889.

COWDREY, S. G., Captain and Assistant Surgeon. Relieved from duty at Fort Bliss, Tex., and ordered to Fort Marcy, N. M. Par. 25, S. O. 104, A. G. O., Washington, May 6, 1889.

FINLEY, JAMES A., Captain and Assistant Surgeon. Relieved from duty at Fort Assinniboin, M. T., and ordered to Fort Totten, Dak. Par. 25, S. O. 104, A. G. O., Washington, May 6, 1889.

DE LOFFNE, AUG. A., Captain and Assistant Surgeon. Relieved from duty at Fort Totten, Dak., and ordered to Columbus Barracks, O. Par. 25, S. O. 104, A. G. O., Washington, May 6, 1889.

TAYLOR, B. D., Captain and Assistant Surgeon. Relieved from duty at Columbus Barracks, O., and ordered to Fort Sill, I. T. Par. 25, S. O. 104, A. G. O., Washington, May 6, 1889.

BROWN, PAUL R., Captain and Assistant Surgeon. By direction of the Secretary of War, is relieved from further duty in the Department of the Platte, and will proceed to Fort Thomas, Ariz., and report in person to the commanding officer of that post for duty, and by letter to the commanding officer, Department of Arizona. Par. 10, S. O. 105, A. G. O., May 7, 1889.

FISHER, WALTER W. R., Captain and Assistant Surgeon. Granted leave of absence for one month. Par. 1, S. O. 30, Headquarters Department of California, San Francisco, Cal., April 27, 1889.

KENDALL, WILLIAM P., First Lieutenant and Assistant Surgeon. By direction of the Acting Secretary of War, will be relieved from duty in the Department of California after he shall have complied with the requirements of Par. 2, S. O. 29, April 24, 1889, from these headquarters, and will then proceed to Fort D. A. Russell, Wyo., for duty at that station. Par. 28, S. O. 104, A. G. O., May 6, 1889.

Official List of Changes in the Medical Corps of the United States Navy for the week ending May 11, 1889.

BEARDSLEY, GROVE S., Medical Inspector. Detached from the Brooklyn, proceed home, and wait orders.

LOVERING, P. A., Passed Assistant Surgeon. Detached from the Brooklyn, proceed home, and wait orders.

NORTON, OLIVER D., Assistant Surgeon. Detached from the Brooklyn, proceed home, and wait orders.

HAWKE, J. A., Surgeon. Detached from the Essex, proceed home, and wait orders.

STOKES, C. F., Assistant Surgeon. Detached from the Minnesota and to the Iroquois.

BRANSFORD, JOHN F., Surgeon. Orders to the Iroquois revoked, resignation accepted to take effect May 4, 1890, with leave of absence granted to that date, with permission to leave the United States.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 11, 1889:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	6	2
Scarlet fever	300	39
Cerebro-spinal meningitis	3	3
Measles	169	9
Diphtheria	165	49
Small-pox	0	0
Yellow fever	0	0
Cholera	0	0

TRAUMATIC SUBDURAL ABSCESS OF THE BRAIN.—From a study of this subject, published in *The Annals of Surgery*, Sir William Stokes has formulated the following propositions: 1. That after the primary symptoms of cerebral traumatism have subsided there is frequently a latent period of varying length, during which there are no distinct brain symptoms connected with abscess-formation whatever. 2. That their appearance is as a rule sudden, and, if uninterfered with, they run a rapidly fatal course. 3. That the occurrence of pus-production resulting from cerebral traumatisms is not incompatible with a perfectly apyrexial condition. 4. That this latter fact will probably aid in differentiating traumatic cerebral abscess from meningeal or encephalic inflammation. 5. That both as regards color and consistence there is great variety in the contents of cerebral abscess-cavities, and that, as shown in Wilm's case, published by Rose, of Berlin, they may become transparent. 6. That antisepticism has largely diminished the risks of the operation of trephining. 7. That, having regard to the great mortality of cases of cerebral abscess when uninterfered with, viz., from ninety to one hundred per cent., the operation is indicated even when the patient is *in extremis*. 8. That in the case where the trephine-opening does not correspond to the situation of the abscess, exploratory puncture and aspiration may be employed. 9. That by the adoption of this measure the necessity for multiple trephine-openings can be largely obviated. 10. That the employment of a blunt-pointed aspirating needle, as suggested by Rentz, is probably the safest mode of exploration and evacuation. 11. That drainage is desirable in the after-treatment of such cases. 12. That both during and subsequent to operative interference in these cases a rigid antisepticism is imperatively required.

HEPATIC SURGERY.—The London correspondent of the *Journal of the American Medical Association* writes that at the Medical Society of London Mr. L Knowsley Thornton gave some notes of his most recent operations in hepatic surgery. The first two were cases of abscess in connection with perforation of the gall-bladder, presumably by gall-stones, though the stones were not found. The third case was one of cholecystotomy, the gall bladder being removed and the stones left in the common duct, from which afterward they were expelled, there being considerable disturbance as they passed through the ileo-cæcal valve. The fourth case was one of ordinary cholecystotomy, the gall-bladder being sutured into the parietal opening and drained. The fifth was one of hepatotomy for hydatids of the left lobe of the liver. The last case was one of abscess in connection with perforation of the gall-bladder, stones being found both in the abscess sac and in the gall-bladder and cystic duct, one hundred in all. Mr. Thornton drew attention to the danger of waiting when there were symptoms of impacted gall-stones, on the advisability of free incision

and drainage in preference to aspiration, on hydatids, on cholecystectomy in place of cholecystotomy, on the function of the gall-bladder, and upon the irritant action of bile on healing wounds. With regard to the two first cases he brought forward, where the stones escaped from the gall-bladder and became encysted, the first tube took about seven or eight weeks to heal up, and was at present quite well.

ACUPUNCTURE IN ENLARGEMENT OF THE SPLEEN.—At the Congress of the Italian Society of Medicine, held at Rome some months ago, Dr. Feletti related two cases of chronic malarial enlargement of the spleen which he had treated successfully by acupuncture. He used steel needles, such as are used for the electro-puncture of aneurisms. Having first carefully disinfected the needle, he plunged it into the substance of the spleen, leaving it there just long enough to be sure that it was in the right place. The procedure is almost painless. In one of his cases Dr. Feletti had an opportunity of examining the organ after death, which occurred (from tuberculosis) a fortnight after the last puncture. With the naked eye small brown spots could be seen in the spleen at points corresponding to the punctures. Microscopic sections showed a roughly triangular area with its base toward the capsule, which at that point was broken; this area was occupied by young connective tissue, together with the remains of a blood-clot. In the discussion which took place on Dr. Feletti's paper, Dr. Fazio spoke highly of the results of parenchymatous injections of quinine in similar cases, which combined the mechanical effects of puncture with the medicinal action of the drug.—*British Medical Journal.*

THYMOL IN TYPHOID FEVER.—At the Congress of Medicine, held in Rome last October, Dr. Testi related his experience of thymol in more than one hundred and fifty cases of typhoid fever treated in the Hospital of Faenza. The results were most satisfactory. The temperature was reduced, not, he maintained, by the withdrawal of heat from the body, as is the case with ordinary antipyretics, but by moderating its production. The antiseptic action of the drug was also marked; it diminished tympanites, checked diarrhœa, and notably lessened the putrefactive products usually found in the excreta. Dr. Testi also states that on microscopic examination he found a remarkable diminution in the number of mucus-corpuscles, epithelial *débris*, and parasitic elements (especially granular) in the stools. The drug has also a marked effect in reducing the excretion of urea, and as it increases the blood-pressure it has no injurious influence on the action of the heart. Dr. Testi strongly recommends thymol in typhoid fever as mitigating the severity of the disease and preventing complications.—*British Medical Journal.*

MOVEMENTS OF THE STOMACH.—Physiologists have long taught the existence of certain peristaltic movements of the stomach which go on during digestion, and have for their object to agitate the alimentary mass and impregnate it with gastric juice, as well as to expel the chyme. Leven even affirms that these movements go on during fasting, though they are more active during the digestive process. Much, moreover, has been learned of late years with respect to the effects of atony of the muscular coat, —an atony the advanced stage of which constitutes gastrectasia, with its formidable array of dyspeptic symptoms. The older physiologists taught that the chemical activity of the stomach is in intimate correlation with the muscular activity, the secretion of gastric juice being the more abundant the more completely all parts of the stomach are brought in contact with the alimentary bolus, the latter reflexly stimulating this secretion. This, as a general rule, is undoubtedly true, being in accordance both with known laws and careful observations, such as those of Beaumont on Alexis St. Martin. It is true that some recent physiologists have inverted the process, and claimed that the energy of the movements of the stomach is closely related to the richness in acid of its contents. To test this, Klemperer, who recently addressed the Society of Internal Medicine of Berlin "On the Motor Functions of the Stomach," has experimented with alkalies, as magnesia, a sufficient quantity of which was introduced into the stomach to neutralize every trace of acid; in these conditions the movements of that organ were found just as energetic as ever. These were, however, healthy subjects, and it would be interesting to note in such subjects the effects of a continuance of these experiments. Certain it is that in another series of experiments, on thirteen patients affected with gastric catarrh, Klemperer noticed that with a diminution of hydrochloric acid and an augmentation of mucus there was a notable diminution in the movements of the stomach. It is probable that the view of Ewald expressed at the same meeting is the correct one, that all the functions of the stomach—secretory, motor, absorbent—constitute a unity or solidarity; that no one of these functions taken separately has the principal part either in the physiological or pathological processes of the organ, while derangement of any one of them sooner or later breaks the harmony and results in disease.

WHISTLING SPEECH.—At a meeting of the Berlin Anthropological Society, Lieutenant Quedenfeldt, a German officer who has lived on Gomero Island, one of the Canary group, described a whistling language which is used by the inhabitants. The language does not consist of any arbitrary series of signals or sounds. It is described as ordinary speech translated into articulate whistling, each syllable having its own appropriate tone. The Gomero uses both fingers and lips when whistling, and Lieutenant Quedenfeldt asserts that he can carry on a conversation with a neighbor a mile off, who perfectly understands all he is saying. The practice is confined to Gomero Island, and is quite unknown to the other islands of the archipelago. The adoption of the whistling language is said to be due to the peculiar geographical construction of Gomero Island. It is traversed by numerous gullies and deep ravines, running out in all directions from the central plateau. As they are not bridged, they can only be crossed with great difficulty; hence a man living within a stone's throw of another in a straight line has often to go many miles when he wishes to see and speak to his neighbor. This, it is conjectured, led to the adoption of whistling as a useful means of communication, which has gradually assumed the proportions of a true substitute for speech.—*Cincinnati Medical Journal.*

PROFESSOR GERMAIN SÉE ON DISEASES OF THE HEART.—Cardiac diseases, according to Dr. Sée (Paris correspondence, *Lancet*), are not distinct from one another. It is the same affection, presenting itself under different aspects, and offering different types. Whether the case be one of subacute or acute endocarditis, ulcerative or vegetating, the disease is always parasitic, and this view leads to a no less revolutionary deduction, that of the negation of their inflammatory nature. Under the latent, and sometimes the remote, influence of a specific disease, especially of articular or choreic rheumatism, the endocardium is exposed to the action of the microbe, easily defined in this part, although not so readily recognized in the joints. At other times the cause is a typhoid fever, or an attack of diphtheria long forgotten, scarlatina, infectious pneumonia, or even syphilis. There is no exception to this rule of the parasitic origin of valvular or myocardial mischief, except in chronic affections of the aortic orifice of old people, which coincide and result from the fatty, atheromatous, and sclerous changes of the arteries. Like all other cardiac diseases, those of the aortic orifice in the young are parasitic. It is degeneration without a trace of inflammation that is found in all heart lesions, whether acute or chronic, and to this condition Professor Sée would give the name of "endocardie." The same parts, the same elements, and the same spots are invaded, the permanent

lesion consisting of a hyperplasia of the conjunctive tissue. The disease is a continuation of the morbid process, which began in an acute or subacute form, perhaps unperceived by the patient or medical attendant. There is, consequently, but one cardiac disease presenting two types—the endocardial and the valvular types. A third type is due to sclerous, atheromatous, and other changes in the arteries, comprised under the general term "arteritis," due to age, alcoholism, gout, diabetes, etc. The fourth type, and to which Sée assigns the most important place, is that condition of the heart which is caused by sclerosis of the coronary arteries, leading to degeneration and narrowing of the vessels, and ultimately to sclerosis of the myocardium—the fifth type. In the sixth class Professor Sée places the hypertrophies and dilatations consequent upon primary valvular disease. The seventh class comprises the nervous troubles. Professor Sée does not think, however, that palpitation and acceleration of the heart's action ever leads to hypertrophy. A pulse of 140 may exist without producing this effect. Nor does exophthalmic goitre lead to the slightest lesion or fatigue. The eighth type is the pericardiac, the cause here being always parasitic. In the ninth and last category come dilatation and aneurisms of the aorta.

Tuberculosis of the Biliary Passages.—According to the Paris correspondent of the *New England Medical Monthly*, M. Toupet showed a liver, at a recent meeting of the Anatomical Society, presenting tuberculosis of the biliary passages and a formation of biliary cavities. MM. Rilliet and Barthez have already described this form of hepatic tuberculosis, and M. Sabourin has made microscopic researches on the subject. The liver shown by M. Toupet presented certain peculiarities not as yet observed. Upon cutting the hepatic canals, these were found to communicate with the biliary cavities; on the walls of these there were grayish granulations, which were simply tuberculous granulations. The communication of the biliary cavities with the large hepatic canals has, according to M. Sabourin, never been observed before. The tuberculous granulations on the wall of the hepatic canals, the existence of tuberculous follicles in the wall of the biliary cavities, were facts which contradict the opinion of Cruveilhier, who considered these lesions as simple angiocholitis.

Precocious Maturity.—The case is recorded by Diamant of a young child who began to menstruate regularly from the age of two years. The menses have taken place up to a short time ago without intermission, and last for five days. The child was born in 1882, and at the end of twelve months had cut all its teeth. In 1886 it weighed fifty-nine pounds, and now in its sixth year it weighs seventy-nine. Till a short time ago it was robust and well. The head and upper extremities are similar to children of its age, but the buttocks and thighs are remarkably developed. The breasts are prominent, and the pubes and axillæ are furnished with hair. The child speaks in a bass voice. Up to January of the current year the health of the child continued good, but since then menstruation has ceased; at each menstrual period the child is seized with epileptiform attacks, and the latter have tended to become more serious both in number and severity.—*Medical Press and Circular.*

Fœtal Blood at Birth.—Dr. Scherenziss, of Dorpat, has published some interesting observations on the condition of the blood at birth. The specific gravity is, he finds, markedly lower than that of the blood in the adult. The hæmoglobin is also much less than in adult blood, the proportion being 76.8 to 100. The amount of fibrin is only about two-sevenths of that in the blood of the mother. Fœtal blood cannot be analyzed quantitatively by washing with saline solutions, a large part of the constituents of the corpuscles, which appear to be in a very loose state of combination, especially the hæmoglobin, going over in the filtrate. Fœtal blood is richer in saline matters than the blood of adults, especially in insoluble salts. The sodium salts are somewhat greater in amount than in the blood of adults, but the potassium salts decidedly less. The sex and the weight of the child appear to have no influence on the quantitative constitution of the blood at birth.—*The Lancet*, November 24, 1888.

The Late Dr. Samuel W. Gross.—At a meeting of the Philadelphia County Medical Society, held April 24, 1889, the following minute was unanimously adopted: "By the death of Dr. Samuel W. Gross this Society has lost an industrious colaborer, a wise counsellor, and the profession one of its most brilliant ornaments. As a student, practitioner, and teacher he possessed, with remarkable surgical acumen, unusual power of analysis and deduction, and his lectures, like his mental workings, were conspicuously clear, concise, logical, and vigorous. He was an earnest student of the progress of surgery in all countries, with more respect for the experience of the present than the traditions of the past; never satisfied to stand still, and ever advancing with the progress of science, he kept his teaching always apace with the rapid strides of surgical knowledge. As an operator he was bold, conscientious, and successful. Possessed of broad views, he was quick to recognize merit and to welcome truth by whomsoever presented. He took an active interest in all that pertained to the welfare of the profession and was ever ready to work for its promotion. He possessed positive convictions and was frank in their expression. As a companion he was genial and entertaining; as a friend, generous and true."

The Boy or the Bag.—Dr. Audley Haslett, of Brooklyn, writes: "Might it not be well to warn readers against a waste of sympathy for the sick boy into and out of whom Professor Silliman is represented as recommending the breathing of six or eight quarts of nitrous oxide gas (Medical Record, April 20, 1889)? His sudden and somewhat irrelevant appearance upon the scene excites a suspicion that he really intruded upon and usurped the place of a 'silk bag,' with which, possibly, the experiments were performed."

Congenital Malformation in an Ancient Egyptian.—At a recent meeting of the Royal Academy of Medicine in Ireland, Professor Bennett exhibited a case of congenital malformation in a mummy. The bones were those of an Egyptian mummy that was many years ago placed in Marshe's Library. There was an extraordinary contrast between the two humeri. The left was perfectly normal, and was apparently that of a full-sized man. The other humerus was very small and stunted, and had at the elbow-end this remarkable peculiarity, that it was wider from condyle to condyle than the bone on the sound side, while the distance between the margins of the articular surfaces was a trifle less. The upper extremity of the stunted humerus articulated with a joint which showed traces of chronic rheumatic arthritis. The joint was evidently one in which motion had taken place.—*Medical Press and Circular.*

Action of Bromide of Potassium on the Nervous Centres.—Drs. Rossi and Agostini have recently made some experiments with a view to determine the action of bromide of potassium on the nervous centres. They gave sixty grains of bromide of potassium daily to a dog weighing about ten pounds. After five or six days it showed some difficulty in movement, and tremor. Later there appeared paralysis of the fore-limbs, and afterward of the hind-limbs, with loss of appetite, diminished sensibility, torpor, and, at the end of fifteen days, death. A chemical examination showed the presence of bromine salts in the brain and cord. There were also evidences of considerable vascular dilatation, with hemorrhages into the vascular sheaths and into the nervous tissue. In the cord there was in addition some swelling of the white fibres with, here and there, a rupture of the fibres.

THE QUESTION OF THE RADICAL CURE OF DEEP URETHRAL STRICTURE.[1]

BY EDWARD L. KEYES, M.D.,

NEW YORK.

GENTLEMEN: It has seemed to me appropriate to lay this question before you that, by an interchange of experience, we may appreciate what views we, as a society, entertain in regard to it, and in how far the innovations in the old operative method, which have of late appeared, promise to be of assistance to us in the future.

My remarks will be confined to organic stricture situated at and beyond the bulbo-membranous junction. Strictures lying in the pendulous urethra have been demonstrated to be capable of radical cure, chiefly by the unceasing and brilliant efforts of Professor Otis. I think that we may all accept it as a demonstrated fact that internal urethrotomy, preferably performed with the dilating urethrotome, will, if the incision be deep enough to extend entirely beyond the outer limit of the stricture-tissue, radically cure organic stricture of the anterior urethra. All honor belongs, in my opinion, to Dr. Otis for having been a pioneer in the demonstration of this fact.

For the deep urethra, however, we are still in the dark, and, notwithstanding claims which appear from various sources, no one is yet in a position to say what, if any, operation will radically cure deep organic stricture, while our daily experience demonstrates that after all operations a cure is usually maintained only at the expense of the occasional introduction of a dilating instrument.

In order to lead up to what I shall have to say later, I must introduce a few words of description here as to what I consider to be the three classes of organic stricture as they are clinically encountered in the deep urethra. They are: (1) The soft stricture; (2) the purely fibrous cicatricial structure; (3) the inodular stricture.

1. By soft stricture I mean very superficial organic lesions, doubtless only involving the surface of the mucous membrane in the deep urethra, the underlying tissues being presumably free from anything more grave than congestion and spasm. I say presumably, because I have no pathological acquaintance with this stricture and only know it clinically.

Clinically it certainly is found. It follows gonorrhœa—perhaps shortly, perhaps remotely. It is generally situated just at the bulbo-membranous junction. It is commonly accompanied by a moderate gleet as one of its symptoms. It yields in other respects all the symptoms of stricture, even to the causation of complete retention. It may not be possible to pass such a stricture with a whalebone filiform bougie used carefully for a long time, and yet a blunt steel sound of moderate size, held properly, will presently in many cases pass with a sudden motion through the obstruction and be grasped upon withdrawal. Blood will often be found upon an instrument so passed.

If now a soft bulbous bougie, a little smaller than the sound, be carefully introduced, it will encounter the obstacle, pass through it after a little manipulation, and upon withdrawal the shoulder of the bulb will catch upon the obstruction and come through with a jump, demonstrating it to exist as a linear organic band. There will usually be blood upon the bulb.

Now immediately, one after the other, conical sounds of increasing sizes can be introduced, until an instrument as large as the urethra will take may be readily passed into the bladder—all this at one sitting.

This I call a soft stricture. You have doubtless all encountered it many times clinically. It is not ordinary inflammatory stricture; it is not simple urethral spasm. Both these elements generally also enter into it, and intensify it, but there is over and above a superficial linear, organic element, often involving, in my opinion, only the surface of the mucous membrane. The organic element is, I believe, very slight.

2. The purely fibrous cicatricial stricture is the traumatic stricture as found in a urethra which has not been the seat of any gonorrhœal inflammation. It may involve only the thickness of the mucous membrane or any extent of the surrounding tissue, even including all the thickness of the perineum and the integument—the latter when the traumatism has directly involved the entire thickness of the perineum, or when subsequent suppuration has destroyed it, occasioned abscess, and burst or been opened externally. This stricture may also be inodular, or it may be devoid of this element and be a clean fibrous scar. It may be unattended by gleet. When such a stricture is inspected during perineal section, the mucous membrane in front of the point of stricture may be found quite healthy. The tissue cuts like true fibrous tissue, like fascia or tendon. The urethra behind is more or less dilated, its surface more or less catarrhal; there may be perineal fistula, but the hard, irregular, ill-defined, lumpy condition of inodular stricture is absent. The fibrous stricture is linear or annular, but clearly defined.

3. The inodular stricture may exist after traumatism, notably in a strumous subject and where there has been considerable suppuration, perhaps burrowing abscess and multiple fistula. The inodular stricture, however, is found in its luxuriance in cases of stricture occurring after gonorrhœa. Such a stricture is lumpy, irregular, ill-defined, tortuous—never linear. The inodular masses of tissue shade off more or less into the surrounding structures. The mucous membrane in front of the stricture, as well as behind it, is generally granular—catarrhal. Gleet is the rule; fistula may be present.

I have tried to give my idea of the types of stricture as encountered clinically. In speaking of the results of treatment I shall refer to them as the soft, the fibrous, the inodular stricture. More or less true inflammatory acute or subacute congestion and thickening may complicate all of them.

Does dilatation ever radically cure deep urethral stricture? That some deep urethral strictures become and remain permanently well after a course of progressive dilatation I believe, from my own experience, to be a fact. I have in my note-books a number of cases formerly treated by myself and by my late partner, Dr. Van Buren, which demonstrate the fact. In one such case, a very good one, which I give as a single example where the test of time was applied, a distinct stricture occasioning chronic gleet existed at five and three-fourths inches, in a man aged twenty-one. The stricture took 14 F. bulb in 1869. I treated it for a number of months, curing the gleet, and passing, finally, No. 28. Then no instrument was passed for twelve years. In 1882 I treated the patient for syphilis. He was perfectly well as to his ure-

[1] Read at the Third Annual Meeting of the American Association of Genito-urinary Surgeons at Newport, May 21, 1889.

thra and did not care to be explored, but I induced him to allow me to try his urethra with 24 F. steel sound. It passed without meeting an obstruction and was not grasped on withdrawal. The patient objected to my trying 28, which was painfully large for his meatus, but I have no reasonable doubt that it would have entered. I assert only, however, a maintenance up to 24, in a urethra which twelve years before had only taken 14, a perfection of function and a maintenance of cure for twelve years without treatment.

This, however, was a soft stricture, and it is only in this class, in my opinion, that a radical cure is at all possible by dilatation. Even in the case of soft stricture relapse is the rule and cure the exception. I believe the difference to depend on the depth of mucous membrane involved in the organic part of the soft stricture.

I do not, from my personal experience, believe that a fibrous stricture or an inodular stricture is ever radically cured by dilatation. I do believe that many of them, of both varieties, may be raised from a small to a large calibre by intermittent dilatation and may maintain enough of that dilatation for a number of years without treatment to allow all the functions to be performed and to cause the patient to consider himself well; but the test of exploration in such a case will clearly show that, while the stricture may not have recontracted enough to occasion symptoms which attract the attention of the patient, yet that it (the stricture) nevertheless exists and has very materially recontracted from the calibre at which it was left upon the cessation of treatment.

Therefore, in a general way, I think it proper to maintain that while it does all that is required in many cases, yet dilatation can only be counted upon to effect and maintain the cure of organic stricture at the expense of the occasional subsequent reintroduction of a dilating instrument for an indefinite period.

Does electrolysis ever radically cure deep urethral stricture? At the last meeting of this society, in Washington, I exposed my experiments with this method, and from the premises decided against it. I have nothing now to add, except that I believe electrolysis may sometimes cure a moderate soft stricture, just as dilatation does, and my impression is that it is in these cases the dilatation, and not the electrical current, that does the work. I am willing to retract this opinion and to believe that electricity may do more when I have the demonstration. I am even willing to admit that possibly a very mild current may perhaps have some merit in overcoming the spasmodic element, in the case of soft stricture.

Internal urethrotomy might cure radically a deep urethral stricture of very moderate extent of the soft, or even the fibrous variety—but on this point I have no evidence to offer.

Does perineal section ever radically cure deep urethral organic stricture? Since the days of Syme, external perineal urethrotomy has been the operation of choice, often of necessity in serious cases, where anything like an attempt at radical cure has been aimed at—but experience has demonstrated that the term radical is not suited to this operation, since a cure must be maintained after it by the use of the sound. This is clearly the rule. I need not demonstrate it, I believe we all recognize it, and we all accept it without trying to explain the occasional apparent exceptions.

My attention has been attracted to some of my own cases, in which I see faintly a possible explanation of the different results that follow perineal section in different cases. I wish simply to raise the point, to call for the experience of others; and to watch more closely, in future—to see whether or not my impression is a correct one. It is quite certain that some strictures, when cut in the perineum, remain open for a much longer time and are much more easily maintained open than other strictures. In what, then, lies the difference? Surely it is not in the amount of cutting done. I cut one gentleman in the perineum entirely through all the urethral tissues up to the apex of the prostate, and forward entirely through the altered bulb, and then (the whole of the anterior urethra being contracted and indurated) I introduced a blunt, straight bistoury, and from the meatus to the continuation of the perineal wound I cut as freely as I dared through the whole length of the floor of the urethra—yet he relapsed. He had already previously been cut in the perineum externally by Van Buren and Gouley, and a number of times had submitted to internal dilating urethrotomy in the pendulous urethra. His strictures were fiercely inodular.

If, then, the difference of result does not wholly lie in the extent of the cutting done it must depend upon the quality of the tissues cut—and this is the distinction I wish to make.

I believe it possible that a purely fibrous stricture in the deep urethra may be radically cured by thorough perineal section, a result which, I believe, may not be usually attained in the case of inodular stricture.

Whether the gonococcus continues to live and thrive as a local irritant in the case of inodular stricture;

Whether a strictly and purely fibrous stricture can ever be other than a traumatic stricture in a healthy urethra;

Whether the inodular tissue can be wholly dissected out and thus leave a traumatic fibrous scar, properly severed by perineal section, to constitute a radically cured stricture, are questions for the future to decide.

My testimony on the subject is not extensive, since I have only quite recently begun to think about the matter—but it is suggestive, and I will detail some cases. They are all taken from private life—no hospital material is used. I have selected a few instances which have not yet been as severely tested as I hope they may be after a longer time, the reason being that my attention was not directed to the investigation, and some of the earlier results that I now record were curiosities to me when I noted them. I did not attempt to explain them at the time.

CASE I.—X——, aged fourteen, was found by me in March, 1873, in bed suffering lamentably from the effects of stricture with over-distended atonied bladder, from which partly decomposed urine escaped only in overflow as the result of constant, painful, straining effort.

In the spring of 1871, two years before, he had fallen upon a fence. I was told that a slough separated from the perineum after urinary retention of many days, both ends of the severed urethra being exposed in the wound. This wound contracted and the boy was cut in the perineum in Boston, but no instrument was passed through the urethra after the operation. After some weeks a catheter was tied in through the urethra, and was retained for three weeks. Later, sounds were introduced a few times, the patient taking ether on each occasion—and then all treatment was suspended.

When I saw him only a filiform whalebone bougie would pass, the bladder was greatly distended, vesical tenesmus was excruciating, only a little urine coming away at a time in drops, the dribbling being constant, but accentuated by a manœuvre which the boy had learned, namely, passing a finger into his rectum and scratching the anterior surface of the gut with his nail. In this manner he had produced a narrow crescentic stricture on the anterior wall of the rectum about an inch above the anus.

Upon a whalebone guide I freely incised the perineum through the scar left by the old incision. I found the stricture to encircle the urethra, to be very tight, fibrous, annular, with no inodular tissue about it. It was a firm, narrow, purely fibrous cicatrix. I cut through it freely upon the roof as well as upon the floor of the urethra. Recovery was promt and uninterrupted. The penis was small, and 21 French was the largest size that I could get to pass the anterior urethra after incising the meatus.

After recovery No. 21 was passed into the bladder, once a week, for about a year, then less often until the intervals became three months.

In May, 1877, a little over four years after the operation, he left town and disappeared from view; considering himself well, he passed no instrument whatsoever.

In May, 1878, five years after the operation, one year after the last introduction of any instrument, he reported well, and I introduced easily into his bladder No. 27 French, six sizes larger than the size to which he had been cut. He was now nineteen years of age, his penis had developed, and the site of the stricture had enlarged along with the rest of the urethra. I have not seen him since.

CASE II.—In October, 1883, I was called by Dr. Fisher, of Hoboken, to see a youth aged thirteen. Two months previously he had fallen upon a fence and ruptured the urethra, while in the South upon a visit. The surgeon who saw him there failed to reach the bladder with a catheter, and therefore drew the urine with an aspirator during four days. Perineal abscess formed. It was opened, but the urethra was not incised.

When I examined the patient no urine passed the meatus, but all escaped in a fine stream through a small perineal fistula as a result of repeated and very severe straining efforts.

Filiform bougies, after prolonged and patient effort, failed to engage at all in the stricture. The scrotum still bore marks of recent inflammatory action; the urine was acid, 1.010, and contained pus and blood.

Aided by Dr. Fisher, I cut this boy in the perineum without a guide. The urethra was absolutely healthy up to a point just within the membranous urethra—the strictured point. The stricture was cut cleanly through in the median line, upon the roof as well as upon the floor. It was annular, circular, fibrous. There was no inodular tissue about it. The urethra behind the stricture was moderately dilated, congested on its surface, and showing a fistulous opening on the floor. This was opened into the original incision.

No. 19 French steel sound was the largest size that could be made to enter the anterior urethra after incising the meatus; the boy had not reached puberty and the genitals were rudimentary.

Recovery took place without accident, and then No. 19 French was introduced into the bladder once a week.

In December, 1885, two years after the operation, the boy called at my office for inspection. The penis had enlarged materially. Every urinary function was perfect, the urine bright and free from pus. No. 19 French had been regularly passed once a week, but no larger instrument.

Recognizing that the advent of puberty had enlarged the urethra, and wishing to test the site of the stricture, I gave the boy 21 French and asked him to pass it. It went easily, and he immediately followed it by a 23, which passed as readily as the 19, and was as large as the meatus would at that time admit. This proved conclusively that the anciently strictured area had increased in size uniformly with the rest of the urethra, and this without being dilated beyond the point to which it had been originally cut. It had increased four sizes in two years.

I ordered the boy from this date to pass 23 French into the bladder once a week. In June, 1886, six months later, he again appeared, with a penis now slightly larger. This time, without trouble, No. 24 was introduced.

At the end of January, 1887, seven months later, he again called, and passed without difficulty No. 25, and then immediately No. 28 French was passed by me to test the urethra. It entered without encountering obstruction, and upon withdrawal was not grasped.

May 11, 1889, two years and three months later, he again called at my request. He had introduced into his bladder a 28 French steel sound, once a week, since his last visit. He was now nineteen years of age, six feet and one inch tall. His penis measured three inches in circumference. I passed No. 30 French into his bladder easily, yet it appreciated slight resistance in the perineum and was moderately grasped upon withdrawal. I then introduced No. 29 metallic bulbous sound. It passed easily, but on withdrawal the shoulder of the bulb was retained by the stricture at four and three-fourths inches, and a little force was required to pull it through. No blood was upon it. In short, here is a case in which a fibrous scar had increased in size, with the development of the genitals, eleven sizes (French) in five and a half years. The scar is, of course, there, and always will be. How retractile it is I shall find out later.

CASE III.—During nearly the entire year 1887 I treated a young gentleman, aged twenty-five, for mild, persistent, relapsing gleet and irritable bladder—and failed to cure him. The meatus had been cut to 30 before the patient saw me, by another surgeon, whose efforts to cure the gleet had been ineffective. The 30 would enter the bladder with difficulty, always bringing blood from a tight band just at the bulbo-membranous junction. I tried to force a larger size, but only succeeded in lighting up a mild cystitis and aggravating the gleet.

This patient urgently insisted upon being cured, as he desired to marry. The gleet and, presumably, the stricture were of gonorrhœal origin. No irrigation, deep urethral instillation, anterior injection, internal treatment, change of air, rest, diet, or the use of No. 30 sound did him any good—therefore I cut him in the perineum, severing the small linear band both on the roof and on the floor of the urethra completely. There was no inodular tissue. This I did in December, 1887.

One year later he visited me in my office, having passed no instrument for eleven months. He was fat and perfectly well in all respects, the urethra dry, the urine like crystal. I passed a No. 33 French steel sound. It entered easily, was not grasped on withdrawal, no blood followed.

This patient is now happily married.

It will be observed that in all these cases the stricture was fibrous, containing no inodular tissue. In two of them the cause was severe traumatism in young boys before the age of puberty, the urethra being uncontaminated by any previous gonorrhœa. In the other, although there had been gonorrhœa, the stricture was a moderate, narrow, dense, fibrous band, without inodular tissue.

I have no such good results to report of any inodular strictures I have treated; and my impression therefore is—an impression stated with all possible reserve—that when the stricture is purely fibrous, especially if there has been no gonorrhœa, and when this stricture is very freely divided, both upon the floor and upon the roof of the urethra, and kept widely dilated during cicatrization—in such cases radical cure is possible after perineal section. Further observation must decide this point. I have only lately begun to consider it. A few years will establish the fact or disprove it. I by no means now positively affirm it.

In inodular strictures various degrees of cure are attained by perineal section. In some cases—with subsequent dilatation for a considerable period—a condition is reached in which the stricture contracts down to a certain point, and there seems to remain, without need for further dilatation. In other cases, after leaving off the use of dilating instruments, the stricture recontracts up to the point of again causing, it may be, complete obstruction of the urinary outflow.

The question of the suture of the urethra—either the immediate suture (after traumatism) of the divided ends of the severed canal, of the divided ends after the excision of the strictured area, or of the floor of the urethra after perineal section, all of which operative methods are much spoken of of late, and praised for their efficacy in hastening cure—has no direct bearing upon the question of radical cure by any method, and therefore the discussion of this important operative method may be ignored for present purposes.

Not so, however, the other two comparatively recent operative novelties, excision of stricture and transplantation of mucous membrane derived from an outside source.

Both these methods, to my mind, open up for us in the future a chance of more often effecting radical cure in the case of inodular stricture than any other means we now possess. I have no personal contribution at present to make regarding either of these methods, but the results claimed fall in so directly in support of my impressions regarding the difference between simple fibrous and inodular stricture that you will pardon me for calling your attention to what has been done by others.

A. Stricker[1] (of Göttingen) first distinctly called attention to the question of the excision of the strictured area of the urethra by publishing, in 1881–82, some operations performed by Professor König, of Göttingen, and alluding to an article published by König (with cases) in 1880.[2]

The next important contribution to the subject is by Heusner,[3] who states that he first operated in 1883, not at the time being aware of König's published work. Heusner's first case was a man, aged thirty-eight, whose membranous urethra had been crushed two years previously. Abscess and cicatricial stricture followed, and one year later perineal section was performed, but the stricture recontracted, so that much distress was experienced and the patient was obliged to resort to the use of a catheter several times daily.

In June, 1883, Heusner dissected out all the strictured area, two centimetres in length, being a portion of the bulbous and of the membranous urethra. The excised portion was lined with granulations and wart-like excrescences. The divided urethral ends were now found to be three centimetres apart. The front end was loosened with scissors from the pubic arch, after which approximation of the severed ends was effected and five points of catgut suture placed to hold them together. A catheter was tied in for twelve days.

No sound was used, as after ordinary perineal urethrotomy. On the thirty-fourth day a No. 24 French catheter passed easily, and one year after the operation the patient in a letter declared himself well, saying that never since the operation had he been obliged to resort to the catheter.

Another case, published previously by Heusner, and treated without sounds, died two and a half years after operation. His stricture had partially recontracted (to size 20), and he died of kidney and bladder disease. Autopsy showed at the site of the operation a fine linear scar.[4]

Surely these results have an important bearing upon the matter under discussion. In Case I. perineal section is a failure, another operation being called for in a year, after which latter the patient reports himself well a year later, not, apparently, having used a dilating instrument meantime. In Case II.—a fine linear scar—somewhat contracted, it is true, but yet admitting No. 20 (F.), is found on autopsy two and a half years after operation.

Wölfler,[5] of Graz, in 1888, details three cases of impermeable urethral stricture which he treated by total excision of the diseased area. He allowed the wound to granulate, and on the eighth day covered the granulating roof and sides of the urethra with strips of mucous membrane (as in Thiersch's method for the skin), several centimetres long, one to two centimetres broad, cut with a razor from the prolapsed uterus of a convenient patient. These strips were not sutured in place, but retained in position by iodoform gauze greased with vaseline and packed in place—the bladder being drained.

Three or four days later, on removing the dressing, the surface was gray and greasy (*schmierig*), looking as if covered with a fine veil. Four or five days later the surface had become a smooth, shining mucous membrane. All the three patients treated in this way recovered, although each, unfortunately, still had a small perineal fistula at the date of report.

The first patient was seen a year after his operation, not having been sounded in the meantime. He is reported as urinating in a thick stream. The second patient had a similar result, but had not been observed so long. After eight months No. 20 (F.) sound passed. The third case died six months after operation—from double nephritis. The continuity of the urethra was found to have been entirely reproduced, so that the boundary where the old and the new mucous membrane came together could not with certainty be determined.

E. Meusel,[1] of Gotha, after excising a stricture in the perineal region, transplanted with great care upon the raw surface immediately, not waiting for granulations, a piece of the patient's inner layer of the prepuce, of twelve square centimetres (5 ctm. long, 2½ ctm. wide), attaching it with four catgut satures at each end to the divided ends of the urethral mucous membrane, and retaining it in place with a woven catheter tied in. On the third day the dressing was changed. On the fifth day thorough inspection showed that the entire flap had taken. The catheter was removed after eight days. A small fistula still persisted at the date of report. Bardenhauer, in a letter to Meusel, states that he has successfully employed this method.[2] A number of other writers have come out in favor of the excision of stricture, notably Poncet,[3] of Lyons, but have added nothing of interest more than I have already detailed.

These results—not absolutely perfect, as it will be seen, since fistula in the perineum remained, although small in extent—these results seem to me to open up for us in the future new possibilities in the way of radical cure.

If we can cut away utterly all inodular tissue in a given case, and either by suturing the divided urethral ends transform an inodular stricture into a linear fibrous stricture, or by transplanting foreign mucous membrane reproduce a portion of the lost canal, we have surely at our command means which, if developed, promise much in the way of effecting radical cure and relieving the patient from the disagreeable necessity of the indefinite occasional use of a dilating instrument on pain of finding his stricture gradually recontract after perineal urethrotomy.

From what has been written, my conclusions are these:

Conclusions.—1. There are three forms of organic deep urethral stricture: The superficial linear fibrous, with inflammatory and spasmodic complications (which I call the soft stricture); the purely cicatricial fibrous stricture; and the inodular stricture, in which there is development of new inodular tissue over and above the true fibrous cicatricial element.

2. Soft strictures are occasionally (but by no means always) capable of radical cure by dilatation—and the addition of mild electrolysis does not prevent this cure by dilatation.

3. Pure linear fibrous stricture, especially if traumatic and occurring in patients who have never had gonorrhœa, may sometimes be radically cured by thorough longitudinal division of the stricture on the roof as well as on the floor of the canal, and by a maintenance of the cure for a moderate time by the occasional passage of very large sounds. I beg to reserve final opinion on this point for a future communication.

4. Inodular stricture does not seem to be radically curable by this method.

5. It seems possible that inodular stricture may be radically cured by a total excision of all the morbid tissue and suture of the healthy divided urethral ends; or, in cases where extensive loss of tissue makes such approximation impossible, by the transplantation (Wölfler's method) of strips of healthy mucous membrane derived from an outside source.

SOME APHORISMS ON THE TREATMENT OF URETHRAL STRICTURE.[1]

By ALEX. W. STEIN, M.D.,

ATTENDING SURGEON (GENITO-URINARY DIVISION) TO CHARITY HOSPITAL, ETC.

THOSE who are brought in daily contact with the hospital interne of the day find that his first surgical ambition is to cut a urethra, and his chief after-thought is how he can immortalize his name, as he believes he will do, by modifying or inventing a new urethrotome; at least this has seemed so to me. It is not my intention, nor have we the time, to discuss all the bearings of the various methods of surgical interference which individual cases of urethral stricture present, but I have thrown together, somewhat hurriedly I admit, some points in treatment which I have laid down in the form of broad propositions, so that we may at once grasp them from the point of individual experience, and, after discussion, formulate, as I am glad it is your intention to do, certain principles of practice which may guide the novice in the treatment of his cases.

The location of the stricture, whether it is in the vicinity of the meatus or near the bulb; the degree of coarctation present; the length of time it has interfered with the expulsive power of the bladder; the degree in which it has crippled the urinary tract back of it, and the character of the stricture as to its irritability or resiliency, have all a most important bearing in determining the method of treatment. Then we have to examine into the general health and temperament of the patient, and in this respect a distinction should be made between the presumed and the actual standard of health. What is considered health by some individuals will be considered anything but health by others. Especially have we to inquire into the manner in which the kidney fulfils its function, before deciding upon any immediate operative interference. The successful issue of the case will depend upon the significance or the interpretation that we give to the presence of adventitious ingredients in the urine. The question of questions, the thread upon which the life of our patient not infrequently hangs: Is the obstruction a greater evil than the remedy proposed? Must we afford *immediate* relief, or is it consistent with safety, is the balance of credit with our patient, if we employ the more *gradual* means at our command?

In the absence of the exact data showing the relative mortality after gradual or continuous dilatation on the one hand, and internal urethrotomy and divulsion on the other, I will offer the following propositions:

1st. Gradual dilatation is unquestionably the safest method of treating urethral stricture. Aside from hemorrhages, abscesses, urinary infiltration, curvature of penis during erection, sloughing of tissue, etc., the not unusual concomitants of internal urethrotomy. Rigors and urethral fever are also exceptional phenomena in gradual dilatation. Most strictures yield to this method promptly and satisfactorily.

2d. The objection usually made to gradual dilatation is that often the patient comes from a distance and seeks speedy relief. To this comes the obvious reply, that we cannot assume risks to the life of our patient in order to save time. But if time is an item, we know what continuous dilatation can do if he will confine himself to the house for a few days.

3d. A urethra that is accustomed to instrumental manipulation, will tolerate incision better than one that is not so accustomed. Should internal urethrotomy be decided upon, our patient is all the better prepared for having submitted to the obtunding effect which the passage of the instruments occasion.

4th. In the pendulous portion of the urethra are strictures often so unyielding and resilient that dilating instruments have little or no effect upon them, and it may be said that the nearer such coarctations are to the meatus, the more do they partake of this character. Such strictures are only amenable to dilating urethrotomy. But I must say, that while it is exceptional to have rigors with an elevation of temperature follow incisions near the meatus, I now recall at least three instances in which a moderate incision of the meatus, without the subsequent introduction of instruments in the urethra, occasioned very distinct rigors and fever. In one patient especially, I had not passed an instrument for eight days previous to the meatotomy, and he had, notwithstanding, a sharp attack of urethral fever immediately after the incision, which gave me considerable anxiety at the time.

5th. Other things being equal, the danger of internal urethrotomy increases with the depth of the stricture, that is, the distance the coarctation is from the meatus. The bulbous portion of the urethra is, from its anatomical nature, the most dilatable, and experience teaches that the nearer the stricture is to the bulb (not traumatic) the more it is amenable to dilatation. At least not until this has been fairly tried and has failed, should incision of this portion of the canal be thought of, and then

6th. External division is to be preferred to the internal in all strictures requiring incision that are accessible from the perineum (notably if of traumatic origin.) In certain quarters across the water our surgical brethren regard the immunity from symptoms, when internal urethrotomy is combined with an external perineal incision; as a revelation; but I think I can speak for you, as I certainly know I can for myself, that we have long since learned that anterior strictures divided internally are rarely attended with unfavorable symptoms (notably urethral fever) when the urine is diverted from them by a perineal opening.

7th. Slight encroachments upon the urethral calibre, when submitted to internal urethrotomy, are not, as a rule, attended with the same inconveniences that follow the operation upon narrow strictures. But strictures of large calibre rarely require cutting, unless indeed a superficial contracting band occasions sufficient reflex disturbances to require prompt relief.

8th. What has been said of internal urethrotomy applies with redoubled force to divulsion, with this addition: First, that it is unnecessary in the bulbous portion, and second, that wherever employed it is dangerous, rude, inexact, and a purely mechanical means that does not exact, and is exempt from, surgical skill. It must be relegated to the dark ages in urethral surgery.

9th. The term urethral fever has been objected to and urinary fever substituted, on the assumption that the absorption of urinary constituents is the chief factor in the genesis of the complaint; but I do not think the choice of the substitute a happy one. The first term, at least, expresses the peculiar and characteristic predisposition on the part of the urethra to resent surgical interference, as no other part of the body does. I believe that urethral fever can, in the majority of instances, be proved to be a vaso-motor disturbance of reflex origin, which we may infer from the fact that severe constitutional symptoms sometimes obtains in cases where the stricture is simply overstretched, and where there is no hemorrhage or other evidence of injury or solution of continuity of any portion of the urethra, whereby the ingress of urinary constituents can result. While the contact of urine with a recently made wound in the urethra is undoubtedly in some way a potent factor in creating constitutional disturbance, it seems improbable that absorption of urine can obtain in sufficient quantity from an epithelial abrasion, produced by the passage of a sound, that is capable of producing in rapid sequence rigors, fever, suppression of urine, uræmic coma, and death. If, in response to a laudable curiosity to ascertain the sensations which the introduction of an instrument occasions in others, we pass for ourselves, the first time, presumably, into a healthy urethra, with the utmost delicacy, a blunt-pointed,

[1] Read before the American Genito-Urinary Association, May, 1889.

moderate-sized bougie, we become conscious of a disagreeable feeling, akin to pain, the moment the instrument enters the fossa navicularis, which becomes more and more intense as we approach the deeper parts of the canal and reach the vesical neck. It may be said that this is caused by a denudation of the epithelium from the mucous surface in opening the lumen of the urethra; and that some injury has been inflicted is shown by the fact that the contact of the urine succeeding the passage of the instrument occasions similar pain. But it must be borne in mind that the irritation is only felt during the contact of the urine, and it subsides too soon (generally after the second act of micturition) to suppose it possible that a reproduction of the epithelium has taken place. Above all, I may well question the ground upon which toxic infection, as a factor in urethral fever, is based, since I find that irritable strictures are often cut with advantage, and without producing any disturbance, although the passage of the sound in dilatation almost invariably occasioned it.

10th. As to ultimate results, thorough dilatation compares most favorably with urethrotomy. An absolutely radical disappearance of a narrow stricture, if it be possible, is of the rarest occurrence. In strictures of large calibre the results are more favorable, whether treated by internal urethrotomy or by dilatation. But there is evidence at hand that the means adopted for the detection of strictures of large calibre are often deceptive in the extreme, and that urethral obstructions are met with where in reality there is absolutely no pathological change in the canal. That such obstructions are always curable we give ready assent to. Then, again, there may be inflammatory thickening or granulations of the mucous membrane sufficient to impart a distinct sense of unevenness or inequality at some point to the manipulator, but in these cases there is often no organization into a stricture. This obtains in many cases of chronic urethral discharge. I am confident to have seen, and so have you, no doubt, thickening of the urethra disappear permanently with the discharge by the repeated introduction of steel sounds of increasing calibre. I have now a number of such cases prominently in mind that were so treated years ago with permanent benefit. That some of the radical cures of strictures of large calibre by internal urethrotomy were of the nature of temporary indurations of the mucous membrane, and not true strictures by organization, becomes thus highly probable. Finally, that some strictures show but little disposition to contract is a logical deduction in favor of internal urethrotomy.

I will not touch upon three or four other methods of treatment which have for their claim a radical cure, for as yet they are *sub judice*, but in the language of Goethe,

> " Ye shall wonders see :
> What has been is not to be ;
> What is said is not to say—
> Before the break of day
> Ye shall wonders see."

AN IMITATION HOSPITAL.—In a Hungarian town the Red Cross authorities had neglected to organize their hospital for two years, when they received notice of an Archducal visitor who would be with them in two days. No time was to be lost; a building was rented for a month and one hundred workmen set to work to put it in order. Beds and other necessaries were borrowed from a real hospital and patients hired. The Archduke declared himself satisfied; but he had scarcely turned his back when the workmen were called in to restore the house to its former condition. The patients were dismissed—but here there was a hitch. They were receiving two florins a day for being sick, and knew they had a good thing. They were put out by force; took their cases into court; the committee was compelled to pay them their wages; and as the affair c me to the Archduke's ears, the originators of the scheme failed to obtain the decorations they expected.

THE MOVEMENTS OF THE THORAX AND LUNGS CONSIDERED IN THEIR RELATION TO CERTAIN PULMONARY DISEASES.[1]

BY J. WEST ROOSEVELT, M.D.,

ATTENDING PHYSICIAN TO THE ROOSEVELT HOSPITAL; VISITING PHYSICIAN TO BELLEVUE HOSPITAL, NEW YORK.

WHILE studying the question of why the tubercle bacillus affects so often the upper lobes I met with many theories depending upon various assumptions in regard to the amount of expansion and contraction of various parts of the lungs. The statement is often made that the upper lobes move less freely than the lower. This alleged deficient movement is said to produce impaired circulation, impaired vitality, etc., and also by some seems, for reasons incomprehensible to me, to be considered an efficient cause either for the inspiration of bacilli by the upper lobes from the air, or for the lodegment of them in the upper by the relatively stronger expiratory efforts of the lower lobes, either in normal respiration or in coughing.

No satisfactory reason, as far as I know, has been given by those who believe that bacteria are drawn into the lungs by the air-currents for the frequent selection of the upper lobes by the tubercle bacilli and of the lower by the pneumococci. Whatever be our views of the etiological significance of the latter, its frequent presence must be admitted. It is rather hard to imagine a "selective action" of air-currents which drives one up and the other down in the air-passages!

It is important to study the chest movements, and for this reason I call attention to certain facts (some of which are, I believe, new) observed by me while going over the subject. The observations throw no light upon the problem presented in phthisis. They rather render it more obscure. They seem interesting, however. It will be seen that most of them are merely repetitions of work done before by others. In spite of this, many of the facts are not generally known.

I call attention especially to the movements of the ribs, since these movements are usually regarded as producing the alleged deficient expansion of the upper lobes.

My observations were made almost entirely upon professional models, male and female, who always were given the idea that they were posing and no mention was made of the respiration. These models were used to posing and used to being nude. Their respiration was probably very nearly normal.

The first point noted was that the profile view of the chest figured by Hutchinson and others is not the one best suited to show the greatest movements. The sternum moves but little, particularly in an antero-posterior direction. The greatest movement seems to be in the neighborhood of the anterior axillary line. A "three-quarter" front view shows the chest expansion to best advantage. From this point also quite considerable backward movement of the lower ribs is often visible. The whole inspiratory movement in healthy subjects consists in moderate elevation of the sternum, with slightest protrusion forward and much greater expansion at the sides, especially near the line mentioned, together, frequently, with some rearward movement of the lower ribs. The abdominal and thoracic types of breathing need not be described. The ribs seemingly are drawn somewhat nearer together, their forward ends elevated, and they appear at first sight to rotate as generally stated.

The motion of the ribs usually described is about two axes; one a line drawn through the head of the rib perpendicular to a line from the vertebral column to the sternum, and the other nearly corresponding to a line drawn from the head of the rib to the sternum. This complicated motion can only take place if the articulations practically form a ball-and-socket joint. Now the ribs are fastened to the vertebral bodies and intervertebral substance by joints which would admit such movements;

[1] Read before the Practitioners' Society, April 5, 1889

but they are also fastened at their necks to the transverse processes. This makes the double movements described almost impossible. True, the attachment at the transverse processes will in the cadaver permit a little movement about the axes mentioned, but it is slight. On the other hand, revolution around a line drawn from the tubercle to the middle of the articulation with the vertebral body is very free. Such a line runs from within somewhat outward, from before backward, from above downward. Now the normal position of the ribs is such that their tips lie much below their heads. The curves of these bones are such that it is almost impossible to describe them. If a rather stout brass rod be bent so that its curves correspond with those of the ribs, and if it be placed in a journal which allows only motion round one axis, and if this axis be inclined so that it corresponds with the line mentioned, it will be seen that movement about this axis reproduces almost, if not quite, exactly the rib movements. If on the cadaver the thoracic contents be removed, together with all muscular structures save the intercostals, and if the ribs be elevated by pulling strings attached to the upper ribs near their middle, movements closely simulating those of normal respiration will take place, the sternum will be elevated and slightly protruded and all diameters of the thorax increased, yet the motion will be seen to take place almost entirely by revolution round the single line drawn through the tubercle and head as described. The following experiment I have not tried on the human subject: A dog, recently killed, was skinned and all the structures about the thorax, save intercostals and diaphragm, removed. Inflation of the lungs by air forced into the trachea produced a similar apparent elevation and rotation of the ribs, yet it could be seen to take place round an axis similar to that described in the human subject.

Drawing lines as described, it will be seen that the axis of the first rib is directed much less backward and more outward than the others. The bone has less downward curve than the rest and also has a longer cartilage than those just below it. This produces more up and down and less lateral movement than the others. The second rib resembles somewhat the first. The third and all the rest, except possibly the tenth and eleventh, move nearly about the axis mentioned.

The costal cartilages, from the third or fourth down to the floating ribs, are attached in such a way that they run in an upward as well as inward direction. As we descend, this upward slant is more marked. This arrangement causes the cartilages to become more horizontal during inspiration, and therefore to permit of much lateral expansion of the chest, while the sternum is not much advanced.

The upper part of the sternum advances, I think, more than the lower, and during forced inspirations the bone seems to bend at the junction of the gladiolus and manubrium. Of course it would be useless or harmful to increase the antero-posterior chest diameter over the heart. It is interesting to note that the triangularis sterni muscle is so attached as probably to help straighten the lower cartilages while holding the lower sternum in.

The next question to be studied is, How much lung is moved by the ribs, and is the motion at any part of the thorax greater or less *proportionally to the bulk of lung-tissue in that part?* Manifestly it makes no difference whether the actual movement of the upper ribs is less than the lower, or whether this movement produces less expansion of the upper lobes than the lower, unless it can be shown that *in proportion to their bulk* the upper lobes expand less.

In the first place, it is hard to say whether any part of a structure like the lung is really more affected by the thoracic movements than any other. Admitting that it is, the upper lobes are much smaller than the lower. Their pyramidal shape is such that slight rib movement should affect them greatly. It is not easy to see that they are at all likely to be less expanded than the lower in respiration. It is interesting in this connection to note that females with the thoracic type of respiration have phthisis in the upper lobes quite as commonly, proportionally to all cases of phthisis in that sex, as males in whom abdominal breathing is the rule. Surely, if there be any difference in the amount of expansion in different lobes, and if the upper expand less than the lower, the difference should be more marked in males than in females. Nevertheless, the bacilli lodge in the upper lobes in females.

The lungs are attached by the ligamenta lata to the sides of the pericardium and to the diaphragm. It is easy to see that it is along this attachment, and along the vertebral column that least thoracic movement can occur. Here, and not in the upper lobes, should we find the evil effects of deficient expansion. Yet we do not have tubercle very frequently here.

I show you a corrosion preparation of the bronchi and of the main branches of the pulmonary artery of an inflated lung. It shows, I think, that the bronchi do not really divide "dichotomously," neither can one exactly agree with Aebey's axial system of branches. The tubes sometimes break up into two, but more frequently send out lateral branches. The main points to which I wish to call attention are: First, that the bronchi and vessels going to the lower lobes lie near the inner surface of the lung, precisely in the region where, theoretically, there should be least motion, and that the main bronchus to the upper lobe runs upward near the inner surface and breaks up into branches, which, on the whole, are nearer this surface than the others; second, it will be seen that in a general way each branch runs so that it lies nearly in the line in which the part of the lung it supplies must move. Thus the tubes and vessels are not bent. It will also be seen that the transverse section of the main bronchi is about proportioned to the amount of lung it is to supply.

The movement of the air in the lungs is a problem so complex that one is astounded at the calm way in which statements are made regarding it by various authors. One thing is clear, however; no more air is inspired than is expired in any lobe. Now, it is frequently said that air is forced into the upper lobes in coughing, etc., so that these become over-distended, and that this air is so driven by the more violent contraction of the lower lobes. If this be so, we must assume that a pressure is produced which must enlarge these lobes in a downward direction against the more violently compressed lower lobes. If so, we must admit that we have in the lower lobes a lessened pressure or this expansion could not occur. Then the lesser pressure must produce the greater! The lungs cannot expand where they are against the chest-walls. The only direction in which they can do so is downward. In regard to theories based upon any peculiarities of inspiration and expiration in the upper lobes, it can only be said that whatever applies to one form of bacterium applies to every other, and that the same is true of fine dust. All bacteria do not show the peculiarity of the tubercle bacillus. Some explanation must be given of why this is so before we can accept the view that there is any peculiarity in the air-currents.

The main points which I have tried to demonstrate are these:

1. It cannot be shown that any part of the lung moves, in proportion to its bulk, in respiration, less than any other.

2. That the part of the lung which actually (not necessarily relatively) must move least is that lying near the inner surface.

3. That it is impossible for the upper lobes to be expanded, in any act of forced expiration, by air driven into them from the lower.

4. No explanation exists of the frequent selection of any lobe by any inhaled bacterium.

How shall I cure my husband of snoring? asks a subscriber's wife. Who will help her?

CLINICAL CONTRIBUTIONS TO THE TREATMENT OF ERYSIPELAS.[1]

By LEONARD WEBER, M.D.,

NEW YORK.

It is about three months since I had to attend a case of erysipelas, which developed upon the nates of a man whom I had operated upon for fistula in ano. Having previously determined to treat the next case of erysipelas that might come under my care according to Wölffler's method, I thoroughly cleansed the part affected, and its immediate vicinity, with corr. subl. $\frac{1}{1000}$, and covered the healthy surrounding skin with several one-inch broad strips of Mead's rubber adhesive plaster, making pretty strong traction and pressure in applying them. To my agreeable surprise, the erysipelas came to a permanent halt at the plaster's *barrière*, and the patient got well again within three or four days from the time of the onset of the attack.

In a paper "On the Mechanical Treatment of Erysipelas," read about six months ago before an Austrian medical society, Wölffler stated that in a series of fifteen cases he covered the part affected, and a narrow border of the sound skin, with traumaticin and ordinary dressings, and in so doing arrested the disease and quickly cured his patients. In his four subsequent cases he applied that method with the same good success which I followed in my own. An explanation of the way in which his mechanical treatment accomplishes its good results he has not been able to give. After gathering this new experience I looked up the literature of the subject to some extent, and was not much surprised to find about as many infallible remedies for the cure of erysipelas spoken of as one may find in reading the history of the therapeutics of diphtheria. It might, therefore, not be out of place to bring this matter before you upon the basis of a moderate number of clinical observations of my own, in order to determine eventually upon one or a few methods which can be applied with a reasonable certainty of success.

About 1863 I became acquainted with, and followed, what may safely be called the English method of the treatment of erysipelas. The diseased and a portion of the sound skin is thickly painted over with liquid tar and covered with cotton, and of the tinct. ferr. muriat. from fifteen to thirty drops are given inwardly every three or four hours. It is seen at once that this comparatively old method is of an antiseptic character to some extent, though nothing was known of Fehleisen's erysipelas coccus when it first came into practice. I have treated a number of cases in this way, as we shall see presently, and have not lost a single one; but I have never brought the disease to an abrupt termination by it.

From autumn, 1866, until spring, 1869, twenty-three cases of erysipelas came under my care at the St. Francis' Hospital of this city. The most of them occurred during the winter months, and were cases of facial erysipelas, the infection starting usually from catarrhal erosions of the nose or mouth or ear. Fourteen of them concerned women, nine men, between eighteen and forty years of age, and they remained in the hospital from ten to twenty-seven days. The general symptoms were rarely severe, of important complications in them I have no recollection, and the disease did not spread beyond the one or the other half of face and head. To these hospital cases may be added about twenty more, which occurred in private practice and which were treated on the same plan, with this difference, that five per cent. carbolic glycerine was applied in loco instead of tar. I will make brief mention of one of these cases, concerning a strong and healthy woman, aged thirty-eight, who was severely ill with an attack of erysipelas of the face and head. She bore up well under daily temperatures of 104° to 105° F., for ten days, lost all her hair after recovery, and the stunted after-growth has remained grayish-white ever since. And another, of a rather fat young man, aged about twenty-three, in whom the facial erysipelas spread rapidly over neck and head, and was associated with high fever. On the fifth day the delirious patient fell into a low adynamic condition, his fast pulse became still faster and small, and he certainly would have died of cardiac paralysis in spite of free exhibition of stimulants and excitants, if two hypodermics of three milligrammes each of digitalis, given six hours apart, had not brought down the pulse and sustained the heart until the fever left the patient, and he finally recovered.

After following this plan of treatment until about 1879, I tried, in the few cases of erysipelas that have come under my observation since, the late Professor Hueter's method, which consisted in hypodermic injections of a few drops of a two per cent. solution of carbolic acid in various parts of the erysipelatous area. My success with them was but indifferent, and it is readily understood why Hueter's method cannot be successful in stopping the disease, when we take into consideration that small groups only of the cocci can be rendered harmless by the various injections.

None of the topical applications thus far spoken of can do more than render some palliative service, and it is a matter of indifference whether we apply a two per cent. or a five per cent. or even a ten per cent. solution of carbolic acid, or a one-thousandth of corrosive sublimate or sublimate collodion, or tar, etc. The great majority of cases of facial erysipelas will get well any way, if the patient be properly taken care of. It is quite another matter with cases of surgical erysipelas of the extremities and the trunk of the body. That there may be danger to life in the course of them is, unfortunately, known too well to necessitate further argument upon it. Should Wölffler's simple method be found generally successful—which I doubt—the application would be as easy as the results were marvellous. Let us see, now, what other surgeons have done of late to arrest and cure the dangerous forms of erysipelas.

Remembering the favorable results which were obtained in Volkmann's clinic in Halle, by multiple cutaneous incisions, in cases of progressive phlegmon, it occurred to Professor Kraske, in Freiburg, to try a similar mode of treatment for erysipelas, and in 1886 he treated three cases successfully in the following way: After thorough cleansing and disinfection of the inflamed surface, he made numerous small incisions, just deep enough to reach the cutis, about one centimetre in length, and from fifteen to twenty to the square inch. This number increased toward the border of the erysipelatous area, reaching into the sound tissues also. The whole surface was then irrigated with a five per cent. solution of carbolic acid, and by gentle pressure the oozing of bloody serum from the tissues encouraged as much as possible. The after-treatment consisted in the application of dressings soaked in a two per cent. solution of carbolic acid, and changed once or twice a day. In two of the cases a single operation was sufficient to arrest the disease, in the third a repetition of it was necessary to effect a cure. Riedel followed Kraske with a series of eleven cases, in which he was successful, with a somewhat modified procedure. He limited his incisions to the border-line of the erysipelatous area, into which he made very fine incisions in great number which were from two to four centimetres long, one crossing the other at an angle of about forty-five degrees, thereby encircling the whole with a framework of cuts. For his dressings he used a one one-thousandth solution of corrosive sublimate, to be renewed three times daily. His cases, like Kraske's, got well within three or four days, and in two of them only was it necessary to repeat the operation. In most of the cases the erysipelatous process was arrested forthwith, and the fever, etc., ceased on the second day of the treatment.

In a paper read before the Medical Society of Hamburg, a short time ago, Dr. C. Lauenstein communicated his obversations on the subject. In his first case he himself was

[1] Read before the German Medical Society of New York, May 6, 1889.

the sufferer, with a severe attack of erysipelas of the arm. He was operated upon by one of his friends after Riedel's method, and the result was all that could be desired. In his second case, Lauenstein observed that the incised sound portions of the skin swelled considerably and turned red, though the erysipelas did not spread beyond them. In his next two cases he therefore laid the incisions in the sound tissues of the border alone, thereby preventing the knife from coming in contact with the infected parts. The result was just as prompt.

The majority of the cases reported by these authors were severe, progressive, and associated with high fever and considerable constitutional disturbance. In some of them the fever continued even after the operation, and the erysipelatous process went beyond the surgical barriers, but its power was not the same as before. The inflammatory processes and suppurations occasionally associated with erysipelas are not influenced by this operation, and have to be treated in the usual way.

The surgical skill required in carrying out this treatment is simple enough to allow any practitioner to do the operation who knows how to handle a knife. Moreover, it would not be difficult for any instrument-maker to make a little instrument with about five very small and sharp little blades, about one centimetre apart from each other with which to operate. Such instrument would both facilitate and expedite the work. Insignificant as the operation is, it would scarcely be convenient, or even possible, to do it without an anæsthetic, on account of its painfulness. In a considerable number of severe cases of erysipelas lives have been saved by it which might otherwise have been lost. To be sure, Wölffler's easy method will be preferable, if further experience should prove it as good as Kraske's; but, so far as I know, his experience has not been confirmed as yet by others in the severer class of cases.

Clinical Department.

FATTY DEGENERATION OF THE VITREOUS BODY.

By FRANCIS VALK, M.D.,

NEW YORK.

In The Medical Record of March 9, 1889, Dr. F. E. D'Oench reports a peculiar case of detachment of the retina, in which he writes of a peculiar appearance of "numerous small white dots, scattered throughout the detached portion, but most numerous near the periphery, apparently of the size of a pinhead or less in the ophthalmoscopic image, and not confluent." These dots, I suppose, were scattered about in the vitreous body and not situated in the detached portion of the retina. If so, I wish to state that I have also under observation two cases, that I would report from my note-book, as follows:

Mr. S. M. T——, aged seventy-three, was sent to me in September, 1888, complaining of spots before the eyes, with constant blurring of the vision, during the past five years. He has no pain in the eyes nor any history of an injury at any time. Says that he has noticed the spots and blurring to have appeared gradually. His distant vision was found to be $\frac{1}{10}$, in each eye, no improvement with glasses. He can read No. 1 Jaeger at nine inches, with + 3 D over each eye.

Also a man, seen at the New York Dispensary, with convergent paralytic squint, left eye, the result of a blow fifteen years ago. The sight in that eye always poor, with occasional attacks of inflammation of some kind. Six months ago he was struck on the right eye with a piece of wood and now has a detached retina with eccentric vision.

On examination of the left eye of each of these patients with the ophthalmoscope, I found the cornea, aqueous, and lens perfectly clear, but as I examined the vitreous body, using convex glasses of different power, I found it spotted with numerous white, glistening spots, situated on all parts of the substance. They appeared to be suspended in the vitreous, with very slight movements when the eyeball was turned upward or downward; while some of them seemed to be held in place by minute, dark filaments that were lost in the substance of the vitreous. These round bodies, being situated at different depths in the vitreous body, as they were brought into focus with a convex glass according to their position in front of the retina, would appear intensely white, surrounded by a dark circle, like an air-bubble under the microscope. Their position was very slightly changed when the eyeball was moved. and they did not sink downward toward the lower part of the vitreous when the eye was stationary.

I have not been able to consult Iwanoff's article on "Fatty Degeneration of the Vitreous," but I am inclined to think that this condition existed in these cases; nor am I familiar with the appearance of the vitreous body in cases of fatty degeneration, though Iwanoff says that this condition is "not of infrequent occurrence," as these are the first cases I have met in my clinical work.

In Soelberg Wells' work on the eye, p. 337, I find in speaking of the vitreous he says: "According to Iwanoff, fatty degeneration of the stroma and cells of the vitreous humor, with subsequent fluidity of the latter, is not of infrequent occurrence, more especially in the aged, in whom it is due to senile decay, and is here a quasi-physiological condition" (*Archives of Ophthalmology*, xv., 2, 4), but he does not describe the ophthalmoscopic appearances of this condition.

Also Dr. D. Webster, in an article on "Synchysis Scintillans" (*American Journal of Ophthalmology*, xii., No. 2), reports a case, as follows: "In the right eye the whole vitreous seems to be studded with small, round, white dots, with a few glistening crystals scattered about among them."

I report these cases as they seem to be the same as that reported by Dr. D'Oench and that we may some day prove what is the pathological condition existing in an eye that presents this interesting appearance with the ophthalmoscope; also if the diagnosis at the head of this report is correct.

ANOMALOUS ACTION OF NUX VOMICA AND STRYCHNINE.

By N. L. NORTH, M.D.,

CONSULTING SURGEON OF THE METHODIST EPISCOPAL HOSPITAL, ETC., BROOKLYN, N.Y.

For many years I have used nux vomica, or its alkaloids, in atonic dyspepsia accompanied or not by irregular action of the heart and constipation of the bowels. As an attendant upon the old people in the Methodist Home for the Aged in this city, I often advise tinctura nucis vomicæ in the failing irregular heart of those in advanced years, either alone or in connection with tinctura digitalis and tinctura cinchonæ comp., and with pleasant results. It is likely that a course of treatment somewhat similar for the conditions named is very generally practised by medical men. It is not advanced as new or strange, but is mentioned to emphasize a condition of the heart occasionally following the use of nux vomica or strychnia, which I do not think is quite so well understood. I mean the production—particularly in the aged—of a very irregular action of an ordinarily correct or very fairly acting heart.

For instance, about three years ago I was called to prescribe for Mrs. S——, about sixty years of age, suffering from indigestion, cardialgia, flatulence, with eructations, etc. The heart was beating quite regularly, and there were no indications of valvular or other disease of the organ. I prescribed a mixture containing, pepsin, bismuth, syrup of ginger, mint-water, etc., with five drops of the tincture of nux vomica to the dose, to be taken

after meals. I was called again hurriedly after two or three doses had been taken, found the patient greatly distressed, respiration disturbed and rapid, and countenance suffused. Applying my ear to the chest, I found the heart in great commotion, contractions very irregular and indefinite, a part of the time intermittent, and again beating with great rapidity. My first thought was a mistake in the medicine, which was withdrawn and alcoholic stimulants substituted. After a few doses of brandy the patient improved, when I ordered small doses of digitalis, and left to visit the drug store to learn how I had written, and how the druggist had compounded, the prescription. To my astonishment I found everything evidently correct, and as I had intended it. My next visit to the patient, on the following day, was a pleasant one, the peculiar symptoms had nearly all disappeared.

The following day I gave again the medicine containing the nux vomica, with a partial return of the agitation of the heart, when the patient herself recognized the symptoms and stopped taking it. I attempted to give the same patient nux vomica on a subsequent occasion, but had to desist, when I set it down as an idiosyncrasy, and explained to the patient that if a strange physician was called to her, to say to him that she could not take nux vomica.

Another case of similar action in this case of strychnia was a gentleman, sixty-five years of age, convalescing from typhoid fever. He had suffered a second relapse, and had had a tedious illness, but had then been for over a week with normal temperature, when he complained of attacks of nausea and faintness whenever he moved or attempted to sit erect. I found his pulse intermittent and irregular. Examining the heart I found great weakness, irregularity, intermissions, etc.; countenance of the patient turgid, suffused, and with a look of extreme anxiety. I could find no cause for the symptoms in the condition of the patient, no complication other than the impending heart-failure, which I fought for days with stimulants of various kinds. Finally I remembered that as he made great objection to enema for his constipation, I had ordered, some days before, a small pill of aloin strychnia ($\frac{1}{60}$ of a grain) and belladonna, of which he was taking, one pill at night, with, occasionally, when his bowels did not answer to it, one morning and night. I withdrew this pill when I called to mind my former experience of a disturbed heart from nux vomica, and my patient rallied from his heart-failure, and has experienced no further trouble from it.

I have just now had a similar case. The patient, a woman, sixty-three years of age, was suffering with acute nephritis, followed with gastralgia, indigestion, constipation, and lastly, almost fatal heart-failure, accompanied with great irregularity, intermission of pulse, suffused purple face, etc. I remembered my other cases, and remembered also that I had been giving to this patient nux vomica with pepsin for her indigestion, and that now I was giving the aloin strychnia and belladonna pill for the constipation, both of which were at once withdrawn, with the abatement of serious heart symptoms and recovery of the patient.

ANTIPYRINE IN LOCOMOTOR ATAXIA.

Dr. A. P. Buchman, of Fort Wayne, Indiana, writes: "I have had under my care a case of locomotor ataxia in which the 'lightning pains' were unusually severe. The chest constriction was most agonizing. Fortunately, I gave a ten-grain dose of antipyrine, with the result of putting my patient at complete rest within an hour. Since then he keeps himself supplied with a quantity of ten-grain antipyrine capsules, and whenever, especially at night, the pains become annoying, one, or at most two, capsules secure a whole night's sleep. I began the use of the antipyrine about the first of March, and my patient has not missed a single night's rest since then."

Progress of Medical Science.

Trophic Disturbances after Resection of Joints.—The following are the conclusions of Dr. V. Rochet, in a paper on this subject published in the *Revue de Chirurgie*, No. 5, 1888: 1. Trophic disturbances of different kinds, and affecting the skin, the muscles, the vessels, and the temperature, have been observed in the corresponding limb after resection of a joint. 2. Some of these disturbances are serious, and compromise more or less the utility of the limb; others are less severe, and for the most part curable. The former have been observed after traumatic resections in military practice, and, speaking generally, after resections effected by imperfect operative procedures, and accompanied by serious technical faults; the latter occur only after well-performed subperiosteal resections practised in cases of disease. 3. Trophic disturbances may occur after other plans of treatment, as immobilization associated or not with counter-irritation and amputation. 4. A well-performed resection is not in itself responsible for the occurrence of these disturbances. Most of these existed before the operation, and are the results of the primary lesions, whether osseous or articular, which necessitated operative interference. 5. The trophic disturbances are to be attributed to two main causes: (*a*) Immobilization of the limb, particularly when effected by bandaging; (*b*) direct or reflex influence of the nervous system. 6. These disturbances undergo, in the long run, a different evolution, according to the nature of the case and the two forms of resection (traumatic and pathological). It would seem on first consideration that the results ought to be better after all traumatic resections, because, apart from the operation, the vitality of the limb had not been impaired in consequence of antecedent lesions. This is really the case when the injury has not caused too much disorder, and when the resection has been properly performed; but frequently, as has been proved by Gurlt, important arteries and nerves have been divided by the original injury, the surgeon has committed serious faults in his operation, or the after-treatment, so important in such cases, has not been properly carried out, and that consequently incurable trophic disturbances have been developed. After a well-performed resection for disease such deplorable results do not occur; on the contrary, the operation has on such cases a most favorable influence. Muscular atrophy, the importance of which is so great with regard to the future utility of the limb, and on which most of the other troubles depend, is very much ameliorated by the operation, unless this condition is too far advanced in consequence of the influence of lesions that existed before the operation. 7. This favorable result of resection performed under the above-mentioned conditions is due to the fact that such an operation removes the two causes of the trophic disturbances; it arrests the inflammatory phenomena and restores the functions of the limb. 8. This last result will be much aided by careful after-treatment, and particularly by willing co-operation on the part of the patient. Methodical exercise of the joint and repeated active movements will do much more than electric currents, massage, and rubbing, which, however, are useful auxiliary means.—*London Medical Recorder.*

Heart-sounds when the Breath is Held.—In a communication to the *British Medical Journal* Dr. J. M. Granville cautions practitioners against what he believes to be a not uncommon source of error in connection with certain conventional modes of examining the heart. The patient is told to "stop breathing." This he does with a more or less forcibly inflated lung, the result being that the contact and impulse elements of the heart-sounds—and we too often forget how large these elements really are—become exaggerated. In addition to this, the lung being not infrequently distended by a very deep inspiration, taken hurriedly at the moment when the patient is told to

"stop breathing," the mechanical obstacle offered to a free passage of blood through the vessels of the lung is especially great. What the listener hears when the patient's breath is held will not be the cardiac sounds, simply unmasked by the suspension of the pulmonary sounds, but the former exaggerated and distorted by the accidental physical conditions of the lungs and the heart, and their surroundings in the thorax; which conditions are abnormal, for a state of forced, or even fixed, inspiration is not normal, and it *modifies* as well as intensifies the heart-sounds sensibly, as any close observer may detect. The very frequent appearance in the consulting room of cases of supposed heart disease, in which, when examined under ordinary conditions, nothing can be discovered to support the hypothesis of disease, may perhaps be to some extent accounted for by the method of examining to which he objects. Another point of moment is the position of the patient. Dr. Granville does not think any physician is justified in affirming the existence of a morbid state until, or unless, he can satisfy himself that the known effects of change of position on the several performances of the cardiac mechanism are produced. It is a matter of very great concern that the number of persons living lives of misery because they have been told that "there is something wrong with the heart" is of late largely increased and increasing; while no inconsiderable proportion of such persons have, in fact, nothing whatever the matter with their hearts beyond, perhaps, some sympathetic disturbance. He is not thinking of the scare produced by "anæmic" sounds, which, by the way, are too often misconstrued even by expert and experienced examiners, but of hypothetical "valvular disease" in hearts which are in no way organically affected, or even the subjects of exceptional muscular debility.

Heredity and Alcoholism.—The Paris correspondent of *The Lancet* refers to a thesis lately submitted by Dr. F. Combemale to the Faculty of Montpellier for the doctorate. It is entitled "La Descendance des Alcooliques," and is divided into three parts. In the first the author studies heredity—"this biological law which, in concert with adaptation, under the guise of transformation, explains the greatest number of physical or psychical facts, physiological or pathological, which one meets in the study of the generation of individuals, of families, of races, and of species." He then sketches the physiological and pathological effects of alcoholism on the individual and on the race. "Alcoholism," he says, "whether it be acute or chronic, exercises on the organism effects manifesting themselves symptomatologically by the diminution of vitality, premature aging of the organs, ending anatomically in premature organic decay by steatosis of the parenchyma or by irritative processes of the serous membranes." But, says the author, its effects do not stop here; heredity transmits temporary or durable characters which a person acquires by abusing, accidentally or habitually, alcoholic drinks. The descendants of inebriates will acquire from their parents, if they are procreated or conceived during a state of intoxication, nervous or physical troubles; and, if they are procreated or conceived during a state of chronic alcoholization, physical or mental alterations in relation with the organic degree of this alcoholization. As to the mechanism of the action of alcoholism, this, according to the author, is explained by the lesions or morbid modifications which the generative organs undergo in all the stages of alcoholism, the greatest effect of maternal alcoholism involving the most intimate connections which bind the product to the mother. The effects of alcoholism on progeniture are treated of in the second part of Dr. Combemale's thesis. Alcoholism of parents, he says, might act on the body and on the health of the descendants in producing deformities, in modifying the exterior characters of the individual, in diminishing his degree of resistance to disease, in producing sterility. It may also and principally act on the intellectual state of descendants, either in producing constitutional states, idiocy, anomalies of the faculties of the mind (will, passion, intelligence), or in producing functional states (mental alienation, delirium, etc.). Dr. Combemale concludes his thesis by a study of the descendants of alcoholic subjects from a medico-legal point of view.

Infectious Jaundice.—Dr. W. P. Vassilieff contributes to the *Ejenedêlnaya Klinicheskaya Gazeta* of St. Petersburg an interestng article on "Infectious Jaundice," founded on observations made in the Alexandrovski Military Hospital in 1883. There were eleven cases, at first somewhat puzzling, of an acute infectious disease, which has recently been described under several different names —typhus hépatique, nephro-typhus biliosus, typhus abortivus cum ictero et nephritide, morbus sui generis, etc. This disease is usually met with as a sporadic affection. There is fever very often at the beginning, then enlargement of the liver and spleen, jaundice, and kidney trouble. The disease usually terminates favorably. From the histories of the eleven cases given by the author it is clear that it is an acute general affection, which commences suddenly with a chill. In some patients nausea, and even vomiting, occurred, after which there were general debility and severe pains in some of the joints, often also in the muscles, especially those of the lower extremities; the appetite was usually bad at the beginning; sometimes there was very great thirst; the patients generally slept badly, and frequently suffered from delirium. When the cases were seen early the temperature was found to be high, the pulse soft and rapid; the tongue was moist and slightly coated; the skin hot and dry. At the beginning there were usually observed enlargement and tenderness of the liver and spleen. Albumen and sometimes casts were found in the urine; also, when there was jaundice, bile-pigment. The lungs sometimes were affected slightly (with bronchitis); in two cases pleurisy occurred. The bowels were usually constipated at the beginning. Later on they were sometimes relaxed, the motions generally being colorless. Frequently at the commencement, and sometimes throughout the whole illness, there were attacks of epistaxis; occasionally also herpes labialis occurred. No micro-organisms could be detected in the blood. The patients, especially when they were admitted in an early stage of the disease, gave the impression of great prostration, but after some days this passed away, and they began to get better. The temperature generally fell about the eighth day, sometimes as early as the seventh, at others as late as the eleventh; sometimes there was a second rise of temperature, which did not usually appear to affect the patient much. Although the disease was of such short duration, the patients after the temperature had fallen appeared to be extremely weak, and regained strength somewhat slowly. Although Dr. Vassilieff has only recorded eleven typical cases, he has from time to time had an opportunity of observing others of a similar character in the hospital. One of these proved fatal; at the post-mortem examination extravasations of blood were found on the serous and mucous membranes, and slough of the mucous membrane of the pharynx. Thirty-six other cases have been described by Landouzy, Mathieu, Weil, Goldschmidt, Wagner, Roth, Aufrecht, Fiedler, and Haas; at least, Dr. Vassilieff has come to the conclusion that his cases and theirs are all examples of the same affection. This disease is met with chiefly in the summer, and nearly always affects working-men, only three cases being on record where the patients were women. It occurs in different parts of Europe in the form of a sporadic, acute, feverish affection, with severe nervous symptoms, and with enlargement of the liver and spleen, functional kidney disturbance, jaundice, and pains in various groups of muscles. In Dr. Vassilieff's opinion, it bears most resemblance to the bilious typhus met with in Egypt and Smyrna and described by Drs. Kartulis and Diamantopulos, and it appears to be a disease *sui generis*, differing from recurrent bilious typhus.—*Lancet*, Dec. 1, 1888.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, May 25, 1889.

A NEW METHOD FOR THE ARREST OF CANCER.

DR. J. INGLIS PARSONS contributes an article to the *British Medical Journal* of April 27th, entitled "Arrest of Growth in Four Cases of Cancer by a Powerful Interrupted Galvanic Current." Dr. Parsons writes in a candid and scientific spirit, and his observations are likely to arouse attention.

Dr. Parsons has a theory that, in cancer, the normal tissue-cells have escaped from the inhibitory control of the nervous system, and hence proliferate. His reasoning is interesting, and is as follows:

"First, with regard to the nature of cancer. The earliest pathologists regarded it as a dyscrasia, or altered constitution of the blood; then followed the embryonic cell theory; finally, the microbe was made to bear the burden of further misdeeds.

"Virchow, with his dogma, '*Omnis cellula e cellulâ*,' demolished the first. The second, propounded chiefly by Cohnheim, will not account for all tumors, even if it be admitted as possible that embryonic tissue can remain for a quarter to half a century in the human tissues, without partaking in the changes undergone by other cells in the body. Third, all attempts to find the microbe have failed.

"The hypothesis now brought forward is founded on the fact that all the cells of the body possess a latent capacity which enables them, under various stimuli, to proliferate and form new tissue. Under normal conditions, this capacity remains dormant, or is only exercised to the extent of keeping pre-existing structures in a living condition. But let an injury or irritation to some part of the body occur, and this latent capacity ceases to be dormant, and an active formation of cells takes place, until the injury is repaired or the irritation removed. Now, this formation of new tissue is essentially a new growth, although not a tumor. The capacity for forming it is common to all the tissues of the body, and it ceases when the necessity for its continuance has disappeared. This appears to show some controlling influence, probably by the nervous system. Is it not, then, possible that all tumors are in the first instance composed of cells formed in the normal process of repair, but that, having escaped from the control of the nervous system, they take an independent life, and continue to proliferate and develop without check, just as all living cells are capable of doing *ad infinitum* under favorable conditions?"

One out of several objections which might be raised to this view is that, according to it, cancer ought to develop in parts of the body deprived by accident or disease of their nervous supply. That this is not the case we know, and it can only be said in reply, that one cannot entirely remove nerve-influence from any part without also entirely cutting off the vascular supply.

Whatever be the theory, Dr. Parsons reports his cases, in which, practically, some interesting results were obtained. Three of the patients suffered from cancer of the breast, one from cancer of the cervix uteri. One of these is reported eight months, one six months, and two three months after the treatment. In all quiescence of the previously active cancerous growth was secured. The technique of the operation is as follows: The patient is anæsthetized; the current is then passed through the tumor and all the tissues for some inches round it by means of fine, insulated needles, so as not to injure the skin. A battery of seventy cells with an electro-motive force of 105 volts is used; the intensity of the current to commence with is 10 milliampères, gradually increased to 600 milliampères, and flashed through the growth in every direction from fifty to one hundred times, according to circumstances. The pulse and respiration were carefully watched. One out of the four cases treated, a woman aged sixty-three, with extensive carcinoma of the left breast, a presystolic *bruit*, and weak, intermittent pulse, was unable to stand more than 250 milliampères, and for this reason: when the current is applied to the left breast electrical stimulation of the heart occurs, and if this organ is healthy, an increase in the strength of its contraction appears to take place after its passage; but with the patient who had cardiac disease the improvement only continued up to a certain point, and then the intermittency increased and great irregularity occurred.

IS CHLOROFORMING BY GAS-LIGHT DANGEROUS?

IN estimating the comparative merits of different anæsthetics, it is very important that we should determine in how far the disastrous accidents, which sometimes occur during the administration of these agents, are due to the conditions under which they are used, and in how far to the peculiar effect of the anæsthetics themselves. In the *Berlin. Klinische Wochenschr.*, February 25, 1889, the question was raised, whether injury can result from the burning of illuminating gas in the chamber in which chloroform is administered. A number of interesting communications on the subject were received by the editor (*Berlin. Klin. Woch.*, March 11, 1889, page 219, and April 1, 1889, page 291), who publishes extracts from them, with the remark that Langenbeck had already observed that "operations by gas-light may become dangerous from the formation of the irrespirable compound $COCl_2$ during the vaporization of the chloroform." The first extract is from Dr. Stobwasser, who states that chloroform seems to form with the gases of combustion a product, which, when inspired, has an extremely unpleasant influence upon the mucous membranes of the respiratory tract, causing irritation of the larynx and trachea, a strong desire to cough, and finally headache. These symptoms appear often half an hour after an operation with gas-light has begun, and disappear only when the person affected passes into another room.

Dr. Iterson writes that, in the past winter he repeatedly observed severe and sudden asphyxia during narcosis in the operating-chamber of a small, new, private hospital, in which on cold days gas was burned to heat the room. When a larger stove was procured and gas was no longer used, anæsthesia was always normal. He had one death, which he ascribed to the combination of chloroform vapors with the combustion gases.

He had just reduced *en masse* a strangulated hernia, in a low chamber, by gas-light, when the patient, who had already returned to consciousness and spoken quite clearly, suddenly ceased to breathe and became cyanotic. All restorative measures were tried in vain. Dr. Fischer says that in his operation-chamber there is a well-constructed gas-lamp, which never vitiates the air when chloroform is not used. During the administration of chloroform in large operations, he observes that, at the end of the first half-hour, one of the attendants begins to cough, and then another, until all present, physicians and nurses, are affected. Besides this strong tendency to cough, which becomes ever stronger, a sense of oppression is felt in the head, then headache, dizziness, etc., and even repeated vomiting appear, and the air, especially about the lamp, seems full of a whitish vapor. These symptoms disappeared on return to the fresh air, but the secretions of the nose and throat were increased, and a subjective unpleasant smell remained for some time. So far, it is not known whether the patient suffered from the bad air or not, as his symptoms after the operation could be attributed to the narcosis. Dr. Hartman mentions similar results in chloroforming under petroleum light, speaking especially of the whitish vapor, which condensed upon his eye-glasses. Ventilation of the room prevented these phenomena.

The above citations indicate clearly a source of danger under the conditions mentioned, of which operators should beware.

The effect upon the patient is interesting. While under anæsthesia, it seems, he is not visibly affected by the vitiation of the atmosphere so evident to the attendants. Sudden asphyxia may, however, supervene, either while he is still narcotized, or when, on recovery from narcosis, the soothing influence of the chloroform is withdrawn from the nervous centres and the respiratory organs.

Whether the deleterious product is formed by the burning of the chloroform vapor, or by combination of the chloroform vapor with the matters formed by the combustion of the illuminating gas, is a question which requires further investigation.

HOSPITAL SURGEONS AND PAYMENT FOR OPERATIONS.

Dr. Henry J. Bigelow, of Boston, has undertaken to show that hospital surgeons should never receive money from patients for operations done in the hospitals they visit. His reasons are that the hospital is a charity, and should be kept as such; and next, that the hospital surgeon is sufficiently paid in *éclat* and experience.

No doubt Dr. Bigelow is right so far as purely charity hospitals are concerned. A surgeon has no right to allow the benevolent public to pay for the board and nursing of patients, while he receives their money in return for the exercise of his surgical skill.

This view, we think, would not be denied by anyone. But in fact, most of our free hospitals have rooms or wards for which patients pay a sufficient sum to give the hospital a handsome margin of profit. The charity element is here eliminated, and Dr. Bigelow's argument is not worth a straw.

It may be true that hospital surgeons are amply rewarded for their services by the *éclat* and experience they gain. It is a curious spectacle to see a physician complaining that his colleagues are getting too much reward for their labor, and arguing for its curtailment. And we are surprised to hear arguments logically so weak and shallow as those raised by Dr. Bigelow, who asserts that "hospital offices would command a considerable premium in money from the best class of practitioners, were they annually put up at auction."

No doubt judgeships, bishoprics, presidencies of various kinds would command premiums in money if put up at auction; but this does not prevent us from paying men who hold such positions suitable rewards for their services.

Dr. Bigelow seems to have in mind a desire to prevent the abuse of hospitals by their drawing cases from the outside practitioner; and he certainly hits at an abuse, though his remedy is one we think likely to increase rather than abate it. If hospital surgeons use their institutions for the purpose of enabling them to do operations more cheaply than those not having hospital facilities, they will do an injustice and an injury to the profession. As a matter of fact, however, patients now who go as pay patients to a hospital, and at the same time fee the surgeon for his operation, may be put to much greater expense than if they were treated at their homes.

THE GROWTH OF THE CHILD'S MIND.

In the last volume of the "Education Series," on "The Development of the Intellect," Mr. H. W. Brown has presented a conspectus of the observations of Professor Preyer on the mind of the child. This conspectus shows chronologically the gradual development of the senses, intellect, and will of the growing child, and presents in a condensed form the result of a great number of careful observations. Many of these results are already well known, but the presentation of them in a systematic and complete way has not heretofore been done.

It is recorded that sensibility to light, touch, temperature, smell, and taste, are present on the first day of infant life. Hearing, therefore, is the only special sense which is not active at this time. The child hears by the third or fourth day. Taste and smell are senses at first most active, but they are not differentiated. General organic sensations of well-being or discomfort are felt from the first; but pain and pleasure, as mental states, are not noted till at or near the second month.

The first sign of speech in the shape of utterance of consonant sounds is heard in the latter part of the second month; these consonants being generally "m," "r," "g," or "t." All the movements of the eyes become co-ordinate by the fourth month; and by this time the child begins to have the "feeling of self," *i.e.*, he looks at his own hands,

and looks at himself in the mirror. The study of the child's mind during the first year shows conclusively that ideas develop and reasoning processes occur before there is any knowledge of words or of language; though it may be assumed that the child thinks in symbols, visual or auditory, which are clumsy equivalents for words. By the end of the year the child begins to express itself by sounds, *i.e.*, speech begins. The development of this speech capacity is, according to Preyer, in accordance with the development of the intellectual powers. By the end of the second year the child's power of speech is practically acquired.

Professor Preyer's most striking and important conclusion, in his own opinion, is that the normal infant can form concepts and perform logical operations without the aid of words, or gestures, or symbols of any kind. He also shows what was known before, that the infant understands spoken language before he can produce the sounds he hears; and finally that the child, before he begins to speak, forms all the sounds that occur in his future speech. Professor Preyer thinks that by his observations he "has bridged over the only great gulf between the child and the brute animal."

The learned Professor does not believe in stimulating the infant imagination by fairy stories or religious myths; but he believes in "Æsop's Fables," and has his son repeat one to him every morning. Such are some of the advantages of being the son of a physiologist.

THE RAPID CURE OF CYSTITIS IN WOMEN.

In view of the fact that this disease is not only very rebellious to treatment, but also occasions at times an amount of suffering, mental and bodily, unequalled by any other infirmity to which the human body is subject, Dr. Madden (*Brit. Med. Jour.*, March 2, 1889) suggests, without apology, an improvement in its treatment which, in his experience, has generally wrought a rapid cure.

Cystitis may, as is well known, be relieved by simple general and local treatment, such as the treatment of dis ease of adjacent parts, the correction of uterine displacements, the relief of renal disease or morbid conditions of the urine. In uncomplicated cystitis warm baths, irrigation of the bladder with soothing fluids through a double catheter, rest in bed, diluent drinks, small frequent doses of Dover's powder, and boracic acid in ten or fifteen grain doses, three times a day, are very useful for the relief of the distressing symptoms. In well-established cystitis, however, more radical treatment is necessary. The method introduced by Emmett, of drainage through an incision through the vesico-vaginal wall, is unsatisfactory, because it is difficult to keep the fistula open, because the irritation of the button is often objectionable, and because a permanent vesico-vaginal fistula, with all its attending evils, may be left.

Dilatation of the urethra for persistent cystitis is a method well known, and of much value in mild cases, but in severe cases it is insufficient alone to produce a cure.

Dr. Madden dilates the urethra with an instrument until he can pass the index-finger into the bladder, and so paralyzes, for a time, the sphincter. It may be necessary to remove the proliferating mucous membrane of the bladder with a dull wire curette. After dilatation, whether the curette is used or not, he makes in all cases local applications of carbolic acid to the mucous surface of the bladder. He applies the carbolic acid in the form of the glycerine of carbolic acid (B. P.), which is quite strong enough. Through his dilator, a bit of absorbent cotton saturated with this preparation is introduced, so that the medicament, without touching the urethra, is brought into contact with the fundus vesicæ. It is allowed to remain there about two minutes, until every part of the vesical wall contracts firmly upon the cotton. The cotton is then withdrawn, and the urethral canal is similarly brushed out with another application of the carbolyzed glycerine. Pain is prevented by the previous application to the parts of a solution of cocaine (ten per cent.). According to his experience, this treatment seldom requires to be repeated more than two or three times, at intervals of a week, to effect a cure of even the most aggravated cases of cystitis in women.

INCREASE OF INSANITY.

At the last meeting of the California Medical Society Dr. J. W. Robertson, of San Francisco, read a paper in which he denied the excessive increase of insanity coincident with higher civilization, and also the importance of the hereditary element. He stated that the records of the Napa Asylum embraced 4,280 cases of insanity, of which 213, or only five per cent., were attributed to hereditary influence. Of the whole number recorded at Napa, 2,700 were males, only 33 of whom were professional men, and only 230 who could be regarded as belonging to the educated classes; 450 were classed as artisans, and the remaining 2,000 were laborers or without active occupation, and very largely of foreign birth. It was stated in the report that, "a large foreign population and a large insane population go hand in hand; and the foreigners in this State (California), who constitute one-third of the population, furnish two-thirds of the insane." Dr. J. H. Brainard, of Los Angeles, stated that he had examined the record of some 8,000 cases of insanity with reference to the influence of education or brain work, and he found that the professions had but a very small representation, the laboring classes being in the proportion of ninety per cent. Against this must be placed the fact that among the seventeen millions engaged in gainful occupations, considerably less than one-fourth could be classed among the professions, or in occupations requiring any high degree of education or mental strain. So that the Napa Asylum statistics really refute the very point attempted to be made. The negro race has 1 insane to every 1,097, the whites 1 to every 505.

A New Hospital Society.—The Society of the Alumni of Charity Hospital held its first regular meeting, Tuesday evening, May 7th. The officers are as follows: *Presiaent*, Dr. Ramon Guitéras; *Vice-President*, Dr. C. W. Stimson; *Treasurer*, Dr. Granville M. White; *Secretary*, Dr. W. L. Baner. The Society already numbers between forty and fifty members. Charity graduates who desire to join should communicate with Dr. Walter L. Carr, 54 West Thirty-eighth Street, Chairman of the Committee on New Members, giving date of their term of service in the hospital.

News of the Week.

AN INTERNATIONAL CONGRESS OF MEDICAL JURISPRUDENCE, under the auspices of the Medico-Legal Society, will be held at Steinway Hall, New York City, on Tuesday, Wednesday, Thursday, and Friday, June 4, 5, 6 and 7, 1889. Morning sessions commence at 10 A.M., and afternoon sessions at 2.30 P.M.

THE MEDICAL SOCIETY OF NEW JERSEY will hold its one hundred and twenty-third annual meeting in the Coleman House, Asbury Park, on Tuesday and Wednesday, June 18 and 19, 1889, commencing at 4 P. M. on Tuesday.

THE AMERICAN LARYNGOLOGICAL ASSOCIATION.—The Eleventh Annual Congress of the American Laryngological Association will be held at Washington, D. C., May 30, 31, and June 1, 1889. A large number of interesting and valuable papers are promised.

THE annual meeting of the Association of Medical Superintendents of American Institutions for the Insane will be held at Newport, R. I., June 18th next.

DEATH IN A CATALEPTIC STATE.—A considerable amount of discussion and sensational writing has been excited by the recent death of the so-called mind-reader, Mr. W. I. Bishop. It is stated that he was suddenly attacked with catalepsy, and very soon died in this condition. An autopsy was performed within six hours. It has been claimed by relatives that it was illegal to do this so soon after death, and, furthermore, that the patient was not really dead at the time. This latter statement may be dismissed as utterly preposterous and absurd. The tests of death are too exact and absolute at the present time to allow of the possibility of such an occurrence at the hands of intelligent physicians. The early performance of the autopsy without the relatives' consent was, we believe, technically illegal, although done with the best intentions. Perhaps some mistake was made in giving out that the death occurred from catalepsy. Such a statement is at least misleading, for catalepsy is but the name for a few peculiar symptoms, and has no claim to be considered a specific disease any more than has headache or hysteria.

THE WORK OF THE GERMAN SURGICAL CONGRESS.—The first day was occupied by Professor Esmarch with an address on cancer. On the second day of the Congress the subject of Professor von Esmarch's lecture was discussed, and a most interesting case of myxœdema was shown, in the discussion of which a prominent part was taken by Mr. Horsley, of London. Dr. Bramann, of Berlin, showed three little boys suffering from symmetrical gangrene, and spoke on the cases. Schinzinger, of Freiburg, caused a sensation by proposing to secure a permanently good result of operations for carcinoma mammæ in young patients by extirpating the ovaries, and thus producing premature atrophy of the glandular tissue of the breast. After communications from Sendler, of Magdeburg, regarding an angioma cavernosum pendulum observed on the mamilla, and from Helferich, of Greifswald, on partial resection of symphysis for removal of a vesical cancer, König, of Göttingen, exhibited calculi produced in the kidneys of dogs by feeding them with oxamide. The morning sitting was concluded by a report from Krause, of Halle, of von Volkmann's method of treating resections of the hip-joint. The afternoon sitting was opened by a lecture from Thiersch, of Leipsic, on excision of nævus. The next speaker was Angerer, of Munich, who spoke on the diagnosis and operative treatment of stenosis of the pylorus. Lauenstein, of Hamburg, gave his own experience on the subject, and the sitting was closed by a lecture from Schlange, of Berlin, on ileus. On the third day, Wehr, of Lemberg, reported on the inoculation of cancer from one dog to another; Schmidt, of Stettin, showed a man whose larynx was totally extirpated two years and a half ago, and who is now well and able to speak intelligibly; Kümmel, of Hamburg, expounded a new osteoplastic operation on the foot; Oppenheim, of Berlin, showed five workmen suffering from traumatic neurosis; Krause, of Halle, spoke on two cases of acute catarrhal suppuration of joints; Petersen, of Kiel, on arthrodesis; Lauenstein, of Hamburg, on total extirpation of the knee-joint; Krause, of Halle, on the treatment of scaly sarcoma; Riedinger, of Würzburg, on malformations of joints; Rydygier, of Krakow, on the suppuration of the inner parts of the nose; Trendelenberg, of Bonn, on the treatment of flat feet and crooked noses; Fischer, of Breslau, on trephining for brain tumors; Höftemann, of Königsberg, on rare cases of trephining; and Gerstein, of Dortmund, on the closure of perforations in the skull. Küster, of Berlin, also spoke on the last subject, and Horsley, of London, on trephining. In the afternoon von Bergmann was re-elected President for 1890. Mikulicz, of Königsberg, communicated his experience in the operative treatment of perforative peritonitis, and was followed on the same subject by König, of Göttingen, who mentioned the extensive experience of American surgeons in this field, owing to the free use of the revolver in the United States. Leser, of Halle, then spoke of a singular case of actino-mycosis, and Pietrzikowsky on the relations of pneumonia to strangulated herniæ. Saturday, the last day of the Congress, was devoted, like the preceding ones, to a series of reports, lectures, demonstrations, and discussions on subjects of deep interest to surgeons, and of high moment to mankind.—*The Lancet.*

THE IOWA STATE BOARD OF HEALTH has decided that Iowa medical colleges, after 1891, should be required to give a four years' course to secure their graduates admission to practice in the State.

CATALEPSY IN A MOTHER AND CHILD.—A case was recently reported in the *Nederlandsch Tijdschrift voor Geneeskunde*, where a pregnant woman became cataleptic, her child suffering from the same affection. The patient was a robust woman, aged forty-four; she had borne eleven children. In youth she suffered from typhus, and after recovery became subject to fainting fits, but throughout her married life she remained strong and well. There was no history of any neurosis in the family. In the seventh month of her twelfth pregnancy she was seized with cataleptic fits, following the loss of a child. Dr. Schoot, of Leeuwarden, found her stiff and motionless. The forearm could be raised and bent with some force, and remained in the same position for about ten minutes, then it slowly fell. The lower extremities could be treated

in the same manner, with the same effect. Consciousness was lost. The pulse was 64, full and regular; the temperature normal; the respirations natural. The pupils, somewhat dilated, reacted to light. On inhaling chloroform the rigidity of the muscles disappeared, and the patient seemed to sleep calmly for four hours. On awaking from the fit the patient remembered nothing that had taken place while it lasted. The fœtal heart-sounds, previously audible, were lost, and not heard till fourteen days before labor. No albumin could be found in the urine. The cataleptic fits occurred about three or four times daily, sometimes there was an interval of two days. Atropine gave the patient a week's repose. The fits continued to term, when she was safely delivered of an apparently healthy boy. Not for four days later did the fits recur. On the fifth day an attack occurred while she was suckling; two days later another fit took place, but no more came on, and three months after labor she was quite well. Shortly after the first attack after labor the child, who had been weaned because of that attack, was seized with disphagia, and could hardly swallow cow's milk. In the evening it had a cataleptic fit. The symptoms were precisely the same as in the mother. The flexibilitas cerea of the limbs was marked. The muscles relaxed during a warm bath, but soon afterward tonic cataleptic convulsions occurred, and the child died after two days' duration of the fits. Dr. Schoot, after due consideration of the differential diagnosis of the case from eclampsia and hystero-epilepsy, came to the conclusion that the fits were cataleptic both in the mother and the child. That they were identical in each case there could be no doubt, but the precise relation of the affection in mother and child remained obscure.—*British Medical Journal.*

Prevention of Diphtheria.—The New York State Board of Health has issued a new circular on the prevention of diphtheria. It contains a statement of the facts now generally accepted regarding the contagiousness of diphtheria, and describes the methods of isolation and disinfection. We observe that sulphur fumigation is recommended, a measure which has apparently been shown to be futile and useless.

The Examinations for License to Practise in Minnesota.—Two years have now elapsed since the present law regulating the practice of medicine in this State went into effect, and the good work of the Board of Examiners has shown itself by the diminished number of quacks now parading their advertisements in the daily newspapers. Out of the ninety-four candidates who have presented themselves for examination up to the present time, thirty have been refused admission to practise.—*Northwestern Lancet.*

Ehrlich's Test for the Urine of Typhoid Fever has been already given in these columns, but at the request of several correspondents we give it again: The following solutions are made: *A*, a saturated solution of sulphanilic acid in dilute (1 in 20) hydrochloric acid; *B*, a 0.5 per cent. solution of sodic nitrite in distilled water. (Both of these solutions must be fresh—especially the latter, which cannot be depended on for more than a week at the longest. When they are mixed, of course, a solution of sulphanilic acid containing free nitrous acid is produced, which is the actual test solution; but on account of the extreme instability of the latter the two solutions must be mixed fresh at each testing.) In using the test, about twenty-five parts of *A* are added to one of *B*. Mix with this an equal bulk of the urine to be examined, and render alkaline with strong ammonia. With normal urine, the only change which ordinarily occurs is a mere deepening of its color to a sherry or vinegar brown. In conditions of pyrexia other than typhoid fever the color also deepens, but still remains merely brown, although usually it becomes of a darker tint than the average color given by normal urines. But when the test is applied to the urine of a patient with enteric fever, the color rapidly turns red, the exact tint it acquires varying from the yellowish-red of bichromate of potassium solution, though ruby red, to a rich port-wine color. On shaking the test-tube a froth is produced which has usually a delicate pink color that is characteristic. On allowing the mixture to stand twenty-four hours the phosphates precipitated have an olive-green tinge. Dr. Howard Taylor, in reporting his experience with this test, evidently is unaware of the importance of this olive-green precipitate.

The Etymology of a Familiar Word.—A correspondent of the *Journal of Cutaneous and Venereal Diseases* writes: "A member of the bar, distinguished alike for his eminence as a jurist and his profound general erudition, gave me recently the etymology of a familiar word that few can correctly spell, and still fewer can trace to its origin. He said the Roman diminutive *ette* contracted to *et* abounds in such words as streamlet, a little stream; rivulet, a little river, etc.; while the Saxon diminutive *ock* serves a similar purpose in such words as hillock, a little hill, and bullock, a little bull, and plural, bullocks, little bulls. So it appears at last that the familiar name by which the schoolboy calls his testicles does not belong to the realm of slang, but descends to us straight from the shelves of mediæval classics."

Dr. Harrison Allen, of Philadelphia, is to deliver the next Toner lecture at the National Museum in Washington, on the evening of the 29th inst. The subject is "The Clinical Study of the Skull, Especially Undertaken in Connection with the Morbid Conditions of the Jaws and Nasal Chambers."—*Boston Medical and Surgical Journal.*

The Hospital Graduates Club gave its fourth annual dinner at the Hotel Hungaria, May 16th. The anniversary address on the natural history of the Hospital Interne was delivered in his usual and felicitously humorous style by Dr. J. S. Hawley. The president, Dr. A. B. Townshend, acted as toast-master. Speeches were made by the following invited guests: Drs. Geo. F. Shrady, D. B. St. John Roosa, R. F. Weir, Frank P. Foster, T. R. Pooley, Geo. H. Fox, R. W. Amidon, Clement Cleveland, Charles I. Pardee, D. Bryson Delavan, L. A. Rodenstein, and others. The club is in a prosperous condition, holding monthly meetings at which scientific papers are read.

The Trustees of the Jefferson Medical College have elected Dr. William W. Keen to the Chair of Principles of Surgery and of Clinical Surgery, rendered vacant by the death of Dr. Samuel W. Gross.

Reviews and Notices of Books.

A Text-book of Pharmacology, Therapeutics, and Materia Medica. By T. Lauder Brunton, M.D., D.Sc., F.R.S., Fellow of the Royal College of Physicians; Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the Universities of Oxford and of London; Late Examiner in the University of Edinburgh, in the Victoria University, and in the Royal College of Physicians, London. Adapted to the United States Pharmacopœia, by Francis H. Williams, M.D., Boston, Mass. Third Edition. Philadelphia: Lea Brothers & Co. 1888.

No words of praise are needed for this work, for it has already spoken for itself in former editions. It was by unanimous consent placed at once among the foremost books on the subject of which it treats, and which was ever published in any language, and the better it is known and studied the more highly it is appreciated. The present edition contains much new matter, the insertion of which has been necessitated by the advances made in various directions in the art of therapeutics, and it now stands unrivalled in its thoroughly scientific presentation of the modes of drug action. No one who wishes to be fully up to the times in this science can afford to neglect the study of Dr. Brunton's work. The indices are excellent, and add not a little to the practical value of the book.

Manual of Chemistry. A Guide to Lectures and Laboratory-work for Beginners in Chemistry. A Text-book specially Adapted for Students of Pharmacy and Medicine. By W. Simon, Ph.D., M.D., Professor of Chemistry and Toxicology in the College of Physicians and Surgeons; Professor of Chemistry and Analytical Chemistry in the Maryland College of Pharmacy, Baltimore, Md. Second Edition, thoroughly Revised and greatly Enlarged. With forty-four Illustrations and seven colored Plates, representing fifty-six Chemical Reactions. Philadelphia: Lea Brothers & Co. 1888.

In this book the author has endeavored to meet the wants of the student of medicine or of pharmacy in regard to his chemical studies, and he has succeeded in presenting his subject so clearly that no one who really wishes to acquire a fair knowledge of chemistry can fail to do so by the help of this work. The manual is divided into seven parts, treating of the fundamental properties of matter, the principles of chemistry, and of the metallic and of the non-metallic elements and their compounds. The remaining sections are devoted to analysis, to organic, and to physiological chemistry. The largest section in the book is naturally that devoted to a consideration of the carbon compounds, or organic chemistry. An excellent feature is the introduction of a number of plates showing the various colors of the most important chemical reactions of the metallic salts, of some of the alkaloids, and of the urinary tests. In the part treating of physiological chemistry the section on analysis of the urine will be found very practical, and well suited to the needs of the practitioner of medicine.

The Dispensatory of the United States of America. By George B. Wood, M.D., and Franklin Bache, M.D. Sixteenth Edition. Rearranged, thoroughly revised, and largely rewritten. With Illustrations. By H. C. Wood, M.D., LL.D., etc.; Joseph P. Remington, Ph.M., F.C.S., etc.; and Samuel P. Sadtler, Ph.D., F.C.S. Philadelphia: J. B. Lippincott Co. 1888.

Over six hundred pages of new matter have been incorporated in the most recent edition of this admirable work, which has intrenched itself so thoroughly in the esteem of physicians and pharmacists alike. This of itself bears ample testimony to the thoroughness with which the exploration of recent pharmacological literature has been undertaken. In its improved condition the work cannot fail to maintain its position in the esteem of the profession.

A Manual of General Pathology. By Joseph Frank Payne, M.D., F.R.C.P., etc. Pp. 528. Philadelphia: Lea Brothers & Co. 1888.

As an introduction to the practice of medicine, Dr. Payne's book cannot fail to serve a useful purpose. The work is divided into two principal parts; the first treating of the processes of disease, and the second dealing with its causes. Besides these main divisions, which constitute the body of the work, there is an appendix devoted to the description of the most approved methods of examining bacteria. A large number of illustrations, many of which are exceedingly well done from wood, serve as useful adjuncts to the text.

Pictorial History of Ancient Pharmacy; with Sketches of Early Medical Practice. By Hermann Peters. Translated from the German, and revised, with numerous additions, by Dr. William Netter. Pp. xi., 184. Chicago: G. P. Engelhard & Co. 1889.

No one can read this interesting little volume without appreciating the enormous strides which have been taken in therapeutics, and particularly in internal therapeutics, a progress largely due, if not entirely due, to the gigantic acquisitions of chemistry. Truly the transition from the nauseous concoctions of the middle ages to the alkaloids of modern pharmacy is immense. The book is written in an attractive style, and is adorned with quaint old engravings illustrating the intricacies of ancient pharmacy.

Physical Development, or the Laws Governing the Human System. By Nathan Allen, M.D., LL.D., Member of the American Medical Association, the American Academy of Medicine, the American Public Health Association, the Massachusetts Medical Society. Boston: Lee & Shepard; New York: Charles T. Dillingham. 1888.

Dr. Allen has been a frequent contributor to magazines and journals, both lay and medical, during the past quarter of a century, the object of his articles being the wider diffusion of a knowledge of the laws of health and of the means of raising mankind to a higher plane of physical development. These essays had naturally been in great part lost sight of, being scattered through the pages of so many periodicals of old date, but have here been brought together in one volume. Most of them are of a very practical nature, treating, as they do, of the laws of longevity and of human increase, of heredity, the prevention of crime and of insanity, of education, sanitary science, consanguineous marriage, and many kindred topics. The author is an original thinker, and he has done a service to his fellows in putting these essays in a form where they are accessible to all interested in social improvements and reforms.

The Relief of Tympanites by Puncture of the Abdomen. By John W. Ogle, M.D., Consultant to St. George's Hospital. 4to, pp. 110. London: J. & A. Churchill. 1888.

The history of this operation is given, as is also the recital of many cases in which it has been done with beneficial results. The opinions are quoted of nearly all the leading English physicians and surgeons of the present generation. Dr. Ogle considers the procedure as positively indicated in many cases. A very fine cannula, thoroughly disinfected, should be used, and the operation should not be delayed too long.

Transactions of the New York State Medical Society for 1888. A handsome volume of nearly seven hundred pages, and a perfect mine of information relative to State medical matters.

SAUNDERS'S QUESTION COMPENDS, Nos. 2–5, inclusive. Philadelphia: W. B. Saunders. 1888.

We have already commented favorably on this series of students' manuals. They are arranged in the form of questions and answers, and are concise, without the omission of any essential facts. No. 2 is on Surgery, by Dr. Edward Martin; Dr. Charles B. Nancrede writes No. 3, on Anatomy; Dr. Lawrence Wolf No. 4, on Medical Chemistry; and Dr. W. Easterly Ashton No. 5, on Obstetrics. A handsome binding, good paper, and clear type increase their attractiveness.

OBSTETRICS, GYNÆCOLOGY, AND PEDIATRICS. By K. N. FENWICK, M.D., Professor of Obstetrics and Diseases of Women and Children, Royal College of Physicians and Surgeons, Kingston, Ontario. 8vo, pp. 251. Kingston: John Henderson & Co. 1889.

IN this work the author has incorporated the substance of his annual lecture-courses, with the usual additions and alterations necessary in such an undertaking. No claim is made for originality. The author's ability at systematic classification is worthy of praise, as well as his faculty of conveying considerable information in a few words.

HYSTERIA AND EPILEPSY. By J. LEONARD CORNING, M.D., etc., New York. 12mo, pp. 176. Detroit: George S. Davis. 1888.

THESE chapters have previously appeared in a less elaborate form in some of the weekly and monthly journals, but they have been elaborated, and now form a condensed, systematic treatise on the topics named. "Hysteria" occupies a little over one-third of the pages, the remainder of which contain observations on epileptic insomnia as well as a description of the general epileptic state. Concerning hysteria, the author notes its frequent occurrence in males, and the clinical evidence against its being regarded as invariably the result of genital derangement. He considers the symptomatology under the headings of psychical manifestations, sensory and motor disorders, and vaso-motor disturbances. Most of the phenomena may be accounted for on the supposition of exaggerated, diminished, or suppressed cortical irritation.

Epilepsy is considered according to the following classification: Grand mal; petit mal; epilepsy, with partial impairment of consciousness and circumscribed muscular spasm; and, lastly, irregular forms of the attack. Dr. Corning's work in neurology has been such as to command careful attention to all he writes, and we confess to a peculiar pleasure on looking over these pages. His theory of treatment by compression of the carotids is well known. Of the conventional bromides he prefers a mixture of the salts of potassium, sodium, ammonium, and lithium. For the epileptic insomnia he recommends full doses of the bromides and prolonged sleep.

THE CAUSATION OF DISEASE: AN EXPOSITION OF THE ULTIMATE FACTORS WHICH INDUCE IT. By HARRY CAMPBELL, M.D., B.S. (London), Member of the Royal College of Physicians, etc. 8vo, pp. 361. London: H. K. Lewis. 1889.

THE title of this book suggests the consideration of a very broad subject, and the author very successfully strives to meet the expectations of the reader. It is, indeed, a philosophical disquisition from beginning to end, general principles being discussed from the broadest and most comprehensive point of view. In keeping with the advanced doctrines of the day he is an evolutionist, in the strictest sense of the term, and a consistent disciple of Darwin, Huxley, and Herbert Spencer. With this understanding of his position the reader is prepared to follow him in the consideration of all those changes of the ages whereby man has evoluted to a more or less perfect animal, and to a comprehensive and thorough understanding of what is meant by the doctrine of the survival of the fittest. Naturally he takes, as the groundworks of application of this doctrine to the causation of disease, the prenatal influences affecting structural changes and their relations to the various environment of the individual. Consequently, as seen by his argument, there is no end to the changes in these regards which may be complementary to each other. Very properly, we think, he takes strong ground in favor of hereditary predisposition, and wisely suggests that this part of the study requires more examination than has heretofore been given it. The framework is laid for much elaboration on the part of the careful student, who, from practical observation, can fill in the gaps so suggestively given with great profit. But it is impossible to do more than sketch the scope of the work, it being sufficient perhaps to say that it is one well calculated to repay a careful perusal by anyone who wishes to obtain a comprehensively broad view of pure philosophical science as applied to the explanation of pathological processes.

THE OPERATIONS OF SURGERY: A Systemic Handbook for Practitioners, Students, and Hospital Surgeons. By W. H. A. JACOBSON, F.R.C.S., Assistant Surgeon, Guy's Hospital, London, etc. 8vo, pp. 990. Philadelphia: P. Blakiston, Son & Co. 1889.

THE volume is very modestly termed a handbook, although from its proportions and contents it lays more claim to being a treatise upon the general subject under consideration. Certainly it is the most complete of its kind that has come under our notice for several years. The arrangement of the topics is very systematic, the treatment of them is terse and practical, while the large number, (nearly two hundred) of illustrations help the reader at once to understand the real technique of the different procedures. The author proves himself to be a judicious operator, as shown by his choice of methods, and by the emphasis with which he refers to the different dangers and complications which may arise to mar success or jeopardize life. Altogether, it is a very good book for the younger and older practitioner, and can worthily hold its place in the first rank of works of its class.

ESSENTIALS OF PHYSICS AND CHEMISTRY. Written expressly for the use of Students of Medicine. By CONDICT W. CUTLER, M.S., M.D., Physician in Chief of the New York Dispensary, etc. Third edition. 12mo, pp. 296. New York: G. P. Putnam's Sons. 1889.

THIS is a manual treating, as its title indicates, of the essentials of physics and chemistry, and is well calculated for the student who may desire assistance in his quiz, or in his final examination for a degree. It is well arranged and very easy of reference.

THE PRINCIPLES OF CANCER AND TUMOR FORMATION. By W. ROGER WILLIAMS, F.R.C.S., Surgeon to Middlesex Hospital, etc. 8vo, pp. 194. London: John Bale & Sons. 1888.

THE chapters of this monograph treat successively of growth, reproduction, evolution of vegetable and animal neoplasms, and etiology. In the first two are elaborated general phenomena, as observed in the lower forms of animal and vegetable life.

In the third and fourth the general doctrine is laid down and defended that pathological new formations in plants and animals can be strictly interpreted in accordance with the doctrine of evolution. "Underlying this is the great principle that the evolution of pathological new formations is but a modified repetition of the normal evolution." All the foregoing chapters are freely illustrated with wood-cuts.

In the final chapter the deductions from the foregoing are brought down to an application; viz., a tumor is the result of the "genesis to excessive activity of certain lowly organized cells of the part determined by local excess of nutrition, the result of intrinsic or extrinsic stimuli."

It is a most interesting book to read, though not in any way suggestive of therapeutic measures except as to the most general good environment.

Society Reports.

THE AMERICAN SURGICAL ASSOCIATION.

Annual Meeting, held in the New Army Medical Museum, Washington, May 14, 15, and 16, 1889.

FIRST DAY, TUESDAY, MAY 14TH—MORNING SESSION.

THE Association was called to order by the President, DR. DAVID W. CHEEVER, of Boston, who delivered the following address:

THE FUTURE OF SURGERY WITHOUT LIMIT.

Fellows of the American Surgical Association: I believe that we are warranted in saying that the future of surgery is without limit. I deduce this conclusion first from considering what the mind of man has already done; second, from the future possibilities of fields hitherto unknown and unexplored, but now opening up to science. There can be but two limitations—either in the mind of man, or in the subject.

Since the time when in the anthropoid the cerebral lobes first began to creep over and cover the cerebellum, what a growth has taken place in the penetrating power of the human senses! The brain has progressed from the rude hammer of the prognathous cave-dweller to the telescope and the microscope. Originally of vision far less acute than the eagle's, the eye of man ranges from the fixed star to the twenty thousandth of an inch bacteria. We analyze the sun's gases with the spectrum; we follow the magnet unerringly on the sea; we utilize the lightning; we count the vibrations of sound; we measure light; we speak across the ocean; we estimate the age of our planet; we analyze atoms; we compose new substances; we make pictures from light; we photograph and map the stars; we explore the pole and test the glacial history of the world; we find subterranean springs and light our homes from old volcanic sources; we measure the crevasses in the glaciers of Mars; we count tides by the moon; we defy the wind with steam; we foretell storms by the barometer; we construct isothermal lines; we inspect the bottom of the sea; we demonstrate eclipses; we measure space by the transit of Venus; we predict comets; we find a solar and a stellar unit of time; we unravel Egyptian chronology; we trace man downward through the stages of evolution. Man invents the wheel, the ship, the pendulum, the siphon; under the water, in and on the earth, in the air, in the infinity of space, in the infinity of microorganisms, the mind finds no limit, but is ever restless, ever searching. And now in medicine averting pestilence, annulling pain, destroying sepsis, shall we stop?

In gradual development the brain of man has gone on step by step, investigating itself, until we localize disease by the tracings on cerebral surfaces, and condense in that wonderful cortical substance a palimpsest of impressions, mental and material. The brain studies itself. Know thyself, said the Greek, and in searching the crypts of the human brain we may well echo the description of the greatest of the sons of men: "How noble in reason! How infinite in faculties! In apprehension how like a god!"

We pass now to the second limitation; in the subject itself. Long since was it said that all was found out in anatomy, and that surgery had nearly reached its limit. Far from this, the microscope has created a new anatomy and a new pathology; physiology changes yearly; the lower animals yield light by the Baconian test of experiment. Anæsthesia enlarged surgery; antisepsis emboldens surgery, and we can set no limits to the advance.

The three sacred cavities, the abdomen, which means the hidden; the thorax, which holds two feet of the tripod of life; the skull, which conceals the nerve-force, the vital principle—all are explored

Medicine, always obscure, is growing clearer, and instruments of precision have been applied to our art; the clinical thermometer is the tell-tale of internal changes, inflammatory or septic. What have we to fear? We advance haltingly, but we advance.

Specialism exhausts minute localities; by its occasional discoveries enlightens medicine; by its failures calls sometimes a halt. Specialism, tempered by general medicine, becomes a safe companion in our march onward.

It becomes us soberly to inquire how to study the new seats of surgical exploration. What new methods are needed; where must we be conservative; where can we be bold? Since medicine is composed of a science and an art, we must study the science to develop the art. The four pure sciences are anatomy, physiology, chemistry, pathology. These purely scientific portions of our profession are the only ones that can yield positive knowledge, and this only by dissections, experiments, and analyses.

Modern surgery deals with anatomical regions hitherto insufficiently studied. First, the *fasciæ*, the linings and bindings of the muscles, vessels, and nerves have great influence in determining the course of suppuration and the size and locality of abscesses. A perfect dissection and preparation of the fascia does not exist. It is, perhaps, impossible to make it. Frozen sections and their photographs give the best idea of the relations of the fasciæ. Familiar instances of the importance of the arrangement of the fasciæ are to be found in the psoas sheath; the saphenous opening; the triangular ligament of the perineum; the deep cervical fascia; the fascia lata; the fascia of the forearm and the annular ligament; the posterior ligament, or fascia of Winslow, in the popliteal space.

Next, the topographical anatomy of the viscera, especially in the abdomen, not only the variations in the reflexion of the peritoneum, but the mobility of the organs; the rhythmic changes produced by respiration on the veins, on the diaphragm as an agent of displacement, and on the pelvic diaphragm, the perineum; the incessant movements of peristalsis and its power to change the locality of organs; all these have not been sufficiently considered by the diagnostician and by the operator. Normal splanchnology and frozen sections of the abdominal cavity are of more worth to the student than the mnemonics of the origin of all the muscles, and the twigs of all the arteries. The exact relations of the mediastina to the œsophagus, aorta, pericardium, and pleural cavities are of great importance also.

No less directly useful is an exhaustive and minute topography of the brain, the bearings of falx tentorium, corpus callosum, ventricles, the centre of decussating fibres, the ultimate origin of the fibres of the cranial nerves, the sinuses, the relations of the middle ear, the petrosal sinuses, the mastoid cells and their variations, the fissures of Sylvius and Rolando.

When we consider physiology we are struck both by its great progress and by its imperfections. The older physiology is obsolete and discarded; but in the newer physiology the functions of some large and important organs are still undetermined. The ductless glands, for instance, the spleen, the thyroid, the thymus, the suprarenal capsules. An ignorance of their functions renders the surgeon unable to predict the consequences of their removal. Of what avail the brilliant operation to excise a double goitre, if it is to be followed by an obscure degeneration of the nervous or glandular systems? Again, in organs of known function, the limit of the digestive power of different portions of the alimentary canal is not yet definitely learned. How can we get along without a gall-bladder? How important is the pancreas? Can the duodenum supplant the stomach in nutrition? How much ileum can be removed without starvation? What will the rectum digest? All these are pertinent questions for the physiologist and have a direct bearing on modern surgery.

In chemistry the whole study of sepsis, antisepsis, fermentation, germicides, the viability of spores is in its infancy, and as certainly as it already has reversed surgical practice, will do so again and again.

The great desideratum of surgery now, if chemistry can supply it, is a new, constant, local anæsthetic. This would enable us to banish a chief cause of secondary shock from our operations.

Finally, in pathology we have much to learn and to influence our surgical practice. Diseased organs change appearance and they change place. A double puzzle is thus presented to the operator. On opening the abdominal cavity we are sometimes at a loss to locate an organ, and even fail to recognize it, so changed is its look and its surroundings. One part is mistaken for another; a sac for intestine; intestine for sac; adhesions for peritoneum, and so in many other instances. It is of the last importance that the operating surgeon should be so familiar with the pathological changes that he can distinguish the false from the true at a glance.

The future destiny of coarse pathological changes of organs, whether they are hopelessly diseased, whether they can recover, whether the affection is organic or inflammatory, is also to be decided rightly or wrongly by the surgical expert on a brief inspection.

Having considered how much we may learn or hope from the pure sciences, we pass to the other limitation of the subject, the arrest or the cure of morbid processes. All surgical disease is inflammatory or organic; we must advance by checking the inflammatory process, or by preventing morbid growths—the first, by averting suppuration; the second by discovering the causes of cell-changes, and cell-proliferation. Through surgical pathology lies the only path. True conservative surgery would then be limited to averting the consequences of traumatism. The earlier labors of Paget and the later ones of Virchow, Pasteur, and Koch, give us some hope of being able to abort suppuration, to inoculate for tubercle; or to eliminate the cancer cell. The abortion of inflammation is now much advanced by the progressing knowledge of asepsis. Pyæmia the opprobrium of surgery has been enormously reduced in frequency. When suppuration has occurred, evacuation, drainage, and antiseptics have been equally successful in shortening the pyogenic process and in promoting repair. In tubercle we see the best results follow the évidement of Sédillot, both in cancerous bone and in suppurating lymphatics.

As in variola, may we not hope that a modified germ may jugulate the tubercle bacillus by inoculation? or if we meet not the success which the modification of rabies is slowly attaining, that chemistry may give us a reagent to devitalize the germ of tuberculosis.

Cancer, to include under that term all recurrent tumors, is by Virchow's nomenclature a misplaced cell-growth. Modern research now gives us hope of finding the cause of this mal-development, and if a germ should be discovered here, a germicide will be finally found.

The manual part of our art, chirurgery, handcraft, requires also to be perfected in connection with the advancing boldness with which we open cavities and feel the pulse of life in its central shrine. New operations demand a new technique, new modes, new instruments, a new code of rules, all to be learned by experiment. Nowhere, perhaps, could the French saying, "jeur chirurgien, vieux medicin," be more applicable. It is to the young surgeon, born and bred in asepsis, that the older physician must look for progress in our art.

In estimating, then, the limitations of surgery, we find none, except they be set by ourselves. How should they be set? By conservative judgment opposed to rashness. In the list of modern and useful operations, as distinguished from the barely justifiable, are the following:

1. To remove growths or foreign bodies from the cavities of the body: Opening the brain; opening the spinal cord; displacement of the upper jaw, or of the nose, for naso-pharyngeal polypi; cutting into the pharynx from outside the neck, to remove tumors of the tonsil; œsophagotomy for foreign bodies; thyrotomy for growths; gastrotomy for foreign bodies; opening the gall-bladder for the removal of stones; opening the pelvis of the kidney for calculi; supra-pubic cystotomy for calculi and tumors of the bladder; ovariotomy; removal of the diseased uterus or its appendages; laparotomy for gun-shot wounds and for extra-uterine fœtation; excision of the lower part of the rectum for growths.

2. To reach and evacuate inflammatory products: Opening the chest and resecting the ribs, for empyæma; opening the abdomen for appendicitis or for chronic peritonitis; opening and drainage of pelvic abscesses, of abscess of the vertebræ; opening of deep abscess of the neck; evacuation and draining abscesses of joints; perinephritic abscess and removal of one kidney.

3. To relieve obstruction: Intubation and tracheotomy; gastrostomy and enterostomy; colotomy; perineal section; herniotomy.

4. To restore continuity: Resection and suture of bowel; resection and union of bone; resection and reunion of nerves; nerve-grafting; reunion of tendons and of muscles.

5. Unclassified procedures: Plastic and osteo-plastic surgery, modifications of orthopedics, including bone sections and excisions; litholapaxy; reduction of dislocation of the hip and of the shoulder by applied anatomy; endoscopy; rhinoscopy and removal of turbinated out growths; pathology and removal of adenoids; aseptic wiring of fractures; local anæsthesia in setting fractures; closing of skull wounds by the insertion of buttons of bone.

6. Operations as yet *sub judice* or on trial: Resection of pylorus; resection of cancerous intestine or omentum; removal of the spleen, of large bronchoceles, of the larynx, the pancreas, the prostate gland, the normal ovary; fixation of the kidney or of the uterus; puncture of the pericardium; opening gangrenous abscesses in the lung; tapping the ventricles of the brain.

Rash statements are to be discounted; rash operations are to be discouraged. The wisdom of our earliest Greek master in analyzing the imperfections of our art holds true to-day: "Ars longa, vita brevis est; occasio fugax, experimentia fallax; judicium difficile." Yet with Bacon came the new light of experiment. In his immortal words: "Recte veritas temporis filia dicitur, non auctoritas." Lean not on authority; the test of truth is time.

The death of Dr. S. W. Gross, of Philadelphia, was reported and Drs. D. W. Yandell, J. Ewing Mears, and P. S. Conner were appointed a committee to prepare appropriate resolutions.

The Committee on Nomination was announced as consisting of Drs. D. Hayes Agnew, William T. Briggs, Hunter McGuire, John S. Billings, and J. R. Weist.

On motion of Dr. L. McLane Tiffany, the Secretary was requested to wire to Dr. T. G. Richardson, of New Orleans, the Senior Vice-president, who was prevented by illness from attending the meeting, the regrets of the Association at his absence.

Dr David W. Cheever, of Boston, read a paper entitled

SARCOMA OF THE TONSIL—EXCISION.

The patient, a male, aged fifty-seven, single, for one year had to breathe through the mouth on account of enlargement of the left tonsil. No pain was experienced until November 1, 1888, when he "caught cold" and the tonsil swelled considerably and became sore and tender, and discharged spontaneously a few days later. At the same time he noticed some enlarged glands in the left neck. The glands gradually increased in size. The tonsil caused no more pain, but there was an increasing sense of fulness behind it, increasing dysphagia, and difficulty in articulation. There was loss of appetite and weight. When he came under observation January 14, 1889, the

left tonsil was found to project nearly to the uvula and was as large as a pullet's egg. There were two glands in the left neck, each as large as a horse-chestnut.

The operation was performed January 17, 1889, ether being given, and the patient being in the sitting posture. A gland in front and one behind the sterno-cleido-mastoid muscle were removed. The first incision was semilunar, concave upward, marking the boundaries of the digastric triangle. A second incision over the lower jaw at right angles to the middle of the first incision was then made. The mylo-hyoid muscle was now divided and the other tissues pushed to one side. The lower jaw was then sawed in two in front of the masseter muscle. The tumor was pressed out by finger in the mouth and was found to be covered with a delicate capsule. On puncture a soft material exuded. The tumor and capsule were removed without great difficulty. There was no hemorrhage, and the facial artery and external jugular veins the only vessels ligatured. The wound in the pharynx was not sutured; the jaw was wired, the external wound in the skin was partially approximated and washed with two per cent. boracic-acid solution and dressed with boracic gauze. The wound was dressed daily. Healing took place rapidly with no unfavorable symptoms. On the thirtieth day the wire was removed and the jaw found to be firmly united. Microscopical examination showed the growth to be round-cell sarcoma.

April 27th, a second operation was performed for a tumor on the same side of the neck. The throat, however, remains healthy. A large glandular mass was removed from the anterior carotid triangle. This also proved to be a round-cell sarcoma.

DISCUSSION.

Dr. D. Hayes Agnew, of Philadelphia: There are several points of interest in connection with sarcoma of the tonsil. I think that, including the case of Dr. Cheever, there are only ten or eleven on record. A second point is the fact of constant recurrence. I believe that there is only one case on record where return has not taken place. In that case the thermo-cautery was employed. Various operations have been employed—the enucleation, the écraseur, the galvano-cautery, the thermo cautery, and the external method first used by Dr. Cheever. The operation when undertaken should be done simply, with the view of palliation. The operation from without is confessedly a difficult operation, and while in the hands of experts it probably affords the best opportunity for the removal of all diseased structure, yet for the general operator some other method would no doubt be better. I have been much struck with the exposure gained by simply slitting the cheek in operations on tumors far back in the throat, as far back as the soft palate. This would probably give as good a chance of success as any other plan of procedure.

Dr. A. Vanderveer, of Albany: The first well-marked case of sarcoma of the tonsil that has come under my observation was in a man aged seventy-two. The tumor had been discovered four months before I saw him. There was a full round tumor of the tonsil, interfering seriously with deglutition and somewhat with breathing. The patient selected enucleation in preference to the operation from the outside. My intention was to remove all that I could with the tonsillitome, cutting from behind forward, then enucleate with a blunt instrument, and use the thermo-cautery. After cutting through the capsule the tonsillitome slipped behind the tonsil and it was completely enucleated. I did not apply the thermo-cautery. The patient had no return of the disease for eight months. The growth then reappeared and rapidly increased in size. Two months later the patient was taken with pneumonia, and died in a few days.

Dr. P. S. Conner, of Cincinnati: I think that the statements in reference to the infrequency of sarcoma of the tonsil are hardly correct. I know of several unreported cases, two of which came under my own observation. One was in a girl aged twenty-six. The disease was so far advanced that I thought no operation justifiable, and she died a few days later. The second case was a man aged forty. The tumor was as large as the fist. I operated by slitting the cheek, and was able to readily separate the tumor from the capsule with the finger. The operation was done in June. In July he was apparently in excellent condition. The disease began to recur in the latter part of August and grew rapidly, and in October he was found dead in bed, supposed to have committed suicide.

Dr. M. H. Richardson, of Boston: Some time ago I removed a tumor of the tonsil by external incision. The enucleation was accomplished with ease, and without opening the pharynx. A year after the operation there had been no return of the disease. This was two years ago, and as far as I know the patient is still living.

Dr. Cheever, of Boston: The operation through the cheek is probably easier and more desirable in some cases, but the operation from the outside leaves less paralysis and less scar. The great dread of these operations—opening the upper part of the alimentary canal—was formerly the danger of fistula. This has now been proven to be without foundation. I am inclined to think that the use of sutures in the pharynx or œsophagus would be more dangerous than their omission. The object of these operations is to permit the patient to die easier. It is more comfortable to die with an external tumor than with one pressing upon the larynx or throat, causing starvation or choking.

Adjourned.

Afternoon Session.

The first paper read was by Claudius H. Martin, M.D., of Mobile, and was entitled

HERNIA: A COMPARISON OF THE VARIOUS METHODS ADOPTED FOR ITS RADICAL CURE—INVITING DISCUSSION OF THEIR RESPECTIVE MERITS.

Reference was first made to the great frequency of this condition. The census reports of 1880 show that of the total number of deaths one in every six hundred was due to hernia; and out of 1,236 deaths from hernia, 141 occurred in children under one year of age. A historical review of the various operations proposed for the radical cure of hernia, from the earliest times down to the present, was then given.

The paper concluded with the following remarks: The ligature of the sac at its neck, with suture of the pillars of canal and ring, may be considered an established surgical procedure. Still, being a comparatively new operation, a discussion of its merits will be of practical value in leading to further improvements, and with them permanent success of the operation. With the present lights before us, the most important point in the operation appears to be the closing of the neck of the sac as high up as possible, so as to effectually seal up the opening into the abdominal cavity. To do this completely, it is necessary that the sac should be carefully separated from the adjacent tissues, and this is not always an easy matter, since oftentimes the true sac is obliterated and a new sac formed in the fibrous tissue, with the vascular and nervous distribution blended in such a manner as to render the dissection most difficult, if not impossible. In such a case Macewen's operation could not be performed, and it would be impossible to twist the sac as recommended by Mr. Ball. This objection does not obtain in crural and umbilical herniæ. Still, since inguinal is the most frequent of the herniæ, it is of importance in them. In the congenital cases it is much easier to separate the sac, and hence more possible to do a complete operation; but since in young children the truss, properly applied and long continued, until the abdominal parieties have become so developed as to increase the obliquity of the canal, will in

most instances produce a permanent cure, all operative procedures in children should be considered unwarrantable. In those cases, however, where an imprisoned testicle complicates the condition, the operation is unquestionably proper, and the removal of the testicle justifiable, and for the simple reason that the presence of the gland in the canal predisposes to the descent of the hernia.

Since the main point in the success of the operation appears to have been the proper disposal of the sac, it is not astonishing that operators who have given it their attention should have adopted diverse methods, each one of which has the same end in view. While Ball twists it, Macewen tucks it up; Hardee insists upon the importance of enclosing the transversalis fascia with the sac in the ligature; J. D. Bryant splits the pillars on either side and weaves in the sac; Annandale opens the canal, ties the sac, cuts it away, and stitches the opening; on the other hand, Stokes opens the sac, and then, stitching the neck, the canal, and the pillars together, he leaves the sac in position; Banks opens the sac, ligates the neck, cuts away the fundus, and sutures the pillars; Alexander, of Liverpool, opens the canal, ligatures the sac flush with the peritoneum internally, then divides the neck below the ligature, leaving the sac in the canal without suturing the ring; MacCormac advocates this plan, while Buchanan cuts down to the sac, slits it up longitudinally on each side of the cord, divides the front part horizontally, rolls up the upper part with which he plugs the internal ring, and turns down the lower half to form the tunica vaginalis.

From a comparison of all the methods, it is apparent that no fixed rule of procedure is established, and although the radical operation is a marked improvement in the treatment of hernia, whether free or strangulated, we cannot consider it perfected, because the methods hitherto resorted to have not proved radical in results. The operation is ideally correct, but the question arises whether, with the uncertainty of success, the risk justifies the operation, especially so if the circumstances of the individual are such that he can content himself with the use of a properly adjusted truss.

DISCUSSION.

Dr. M. H. Richardson, of Boston: My experience with the operation for the radical cure of hernia has been small. Sufficient time has not elapsed to permit us to say what the ultimate result will be. My preference has been for the invagination of the sac as proposed by Macewen. I do not advocate the operation in trivial cases of hernia. Here I believe that the application of a well-fitting truss is the more conservative and better plan.

Dr. D. Hayes Agnew, of Philadelphia: We yet have to speak with a good deal of reserve as to which is the most successful operation. Sufficient time has not elapsed to enable us to speak positively upon this subject; the operation which seems to me most applicable is that in which the sac is ligated, pushed into the internal ring, stitched there, and transverse sutures passed across the canal. I think that the omentum will constitute an important element in the radical cure of hernia. I believe that in all cases of strangulated hernia we are justified in attempting the radical cure. The same is true in those cases of hernia which cannot be controlled by a truss, leaving the patient exposed to great risk.

Dr. W. W. Dawson, of Cincinnati: In cases where life is not in jeopardy we should approach the operation with a great deal of consideration. I have seen very different results from the same operation performed with equal care in cases apparently similar. Where life is in danger duty impels us to operate; but where the question is one of æsthetics or abridged usefulness, the operation should be approached cautiously.

Dr. L. McLane Tiffany, of Baltimore: My operations for radical cure in cases of strangulated hernia are more successful than formerly, and I attribute this to the fact that I operate now in a more cleanly manner. I think that no operation for strangulated hernia is complete unless an attempt at radical cure is made. Where the hernia is not strangulated, the question arises as to the kind of hernia, the inconvenience that it causes, and the circumstances of the individual. I do not believe that the operation *per se* is likely to be followed by much trouble. The method to be employed must be determined by the peculiarities of the case. In regard to children, I think in congenital hernia, especially where it is probable that the child will have to work for its living, that it is the duty of the surgeon to operate. Here it is not necessary to open the peritoneum. A ligature is thrown around the sac above and another lower down, and the intervening portion excised, forming a tunica vaginalis below and a peritoneal sac above.

Dr. D. W. Yandell, of Louisville: I believe that in strangulated hernia the surgeon should attempt the radical cure. This has been my practice and I have used various methods. It is difficult for any one man to decide which is the best operation, but in the course of ten years we shall be able to arrive at some opinion. At present, it is simply historical and no one can say which is the best method.

Dr. J. Ford Thompson, of Washington: So far as my experience has gone, I think that there is very little difference in the operations; the main point is to get rid of the sac. I think that suture of the pillars is useless; the operation that I have employed is practically that of McBurney. In strangulated hernia it seems to me that there must be danger in inverting the sac as in Macewen's operation. I have seen many cases of hernia in children, but I have never been able to adopt the view of Dr. Tiffany. As a rule, if we can keep the intestine reduced, the hernia is cured in a comparatively short time. In some cases of large hernia in children, the radical operation is probably justifiable.

Dr. W. W. Keen, of Philadelphia: We doubtless all agree that in strangulated hernia, no operation is complete without an attempt at radical cure. We also agree that in those cases where the hernia is not controlled by a truss, and the patient is unable to labor, radical operation is advisable. The tendency at the present time is to extend the limits of the operation beyond these two classes. The presence of hernia is always attended with risk; hence the tendency at present is to operate on a large number of cases. In children, if the retentive measures after a thorough trial for a few years fail to effect a cure, I should be inclined to operate.

In very large hernia, I should not be inclined to use Macewen's method. The life of the sac is imperilled by separating it. In large hernia a certain amount of preparatory treatment is desirable to accustom the abdominal cavity to the presence of the intestine, and thus prevent undue pressure upon the diaphragm and strain upon the sutures. In the more ordinary cases, I think that the operation of McBurney is the best. I should place the operations in the following order: McBurney's, Macewen's, and Ball's.

Dr. C. H. Mastin, of Mobile: I have little to add. The object of my paper was to elicit discussion as to the best method of operating. I have performed thirty four operations for hernia, with three deaths. Two of these may be excluded, as the patients were *in extremis* at the time of the operation. This leaves thirty-two cases with one death. Of this number, there have been eight radical cures. One of these cases I have watched for seventeen years. The method employed was after the sac was opened to pass a deep pin through the pillars, with an ordinary twisted suture over it, close the incision, and place the leg on a double inclined plane. Thirty-one cases have recovered with primary union. I believe that the cure is produced by the dense cicatricial tissue formed in the canal.

Dr. J. R. Weist, of Richmond, Ind.: I have operated on strangulated hernia forty-one times. In thirty cases I have attempted to make a radical cure, using a variety of

methods. In only four cases have I succeeded in keeping the hernia in. A number have remained well for six months to two years, and then the hernia has reappeared as bad as ever.

Dr. M. H. Richardson, of Boston, read a paper entitled

THE SURGICAL TREATMENT OF GANGRENOUS HERNIA.

The principal question discussed was the relative advantage of immediate excision and suture of the bowel, and the formation of an artificial anus with subsequent closure. The views of various authorities were first quoted. The author then briefly reported the cases coming under his own observation.

Case I.—A young woman with right femoral hernia, strangulated for one week. Bowel was found gangrenous and excised. Death from shock the next day.

Case II.—Woman, sixty-five years of age, left inguinal hernia. On opening the sac the bowel was found strangulated and dark in color. The hernia was reduced, but the symptoms of obstruction continued and five days later the sac was opened and the intestines found strangulated by a band within the ring. The bowel was drawn out, the strangulated portion excised, and the ends sutured. The patient died of shock.

Case III.—Woman, forty-two years of age, had been treated by Christian Scientists for five days. There was a large umbilical hernia, with gangrenous intestine. The sac was filled with fecal matter. The constriction was found and the bowel drawn out and excised beyond the constriction and the ends united. This patient recovered perfectly and has remained well.

Case IV.—A woman with enormous umbilical hernia, with strangulation and gangrene. The fecal abscess opened by natural processes and the woman has been in perfect health since, with the exception of the artificial anus. This will be operated on next week.

In the two cases of excision the time required for the passage of the sutures was twenty minutes; the whole operation did not exceed one hour. The longer the operation the more are the chances reduced.

Reference was then made to the use of the bone plates of Senn and the catgut rings of Abbe. These devices may do more in such cases than anything else. Every case must be decided on its merits. The danger to life of resection in suitable cases is probably not greater than the danger of artificial anus with the dangers attending the subsequent closure of the same. The danger of the latter operation is especially great when the opening is near the stomach. Artificial anus is also objectionable on account of the excoriation of skin which attends it, and also the risk of giving way of the sutures.

The author concluded as follows: It seems to be the general opinion of surgeons everywhere that, under some circumstances, excision and suture are justifiable. It seems to me that the primary operation should only be done where all the conditions are favorable. It is pre-eminently a hospital operation. Every appliance and preparation should be ready for its most perfect performance. It is not an operation to be recommended to the general practitioner or to the unqualified operator. It depends for success more often upon rapid and skilful execution than almost any other operation.

There is no doubt that in some cases this procedure is imperative, where the part necrosed is too high up for intestinal nutrition to be maintained. The difficulty, of course, is to recognize this state of things. Even when it can be demonstrated that the jejunum is gangrenous, excision is not justifiable unless the patient's condition offers some hope, and there is a chance that the relief of the symptoms of obstruction may be followed by sufficient improvement to make a secondary operation possible.

DISCUSSION.

Dr. D. Hayes Agnew, of Philadelphia: My experience is too limited to enable me to say much upon this subject. I recall three cases of gangrenous hernia. One was a case of inguinal hernia in which I excised a portion of the bowel. The patient recovered from the immediate effects of the operation and passed out of my hands. Some months afterward he was advised by another surgeon to apply a compress to the external opening so as to compel nature to establish a communication between the two portions of bowel. He did so, with fatal results. The second case was one of femoral hernia which had lasted six or seven days. It was laid open and the patient recovered. As the granulations filled the opening, communication took place between the two portions of bowel. The third case was one of umbilical hernia. I opened the sac, excised ten inches of intestine, and carefully stitched the ends. The patient died of hemorrhage at the end of two days. It occurs to me that it would be wiser in such a case to stitch the intestines to the skin and at a subsequent period do this operation of Dr. Abbe.

Dr. William T. Briggs, of Nashville: Although I have seen many cases of strangulated hernia, I have seen but three instances of gangrenous intestine. In the first case I opened the abscess and the fecal contents escaped. The patient lived some time, but died of inanition. In the second case I attached the bowel to surrounding parts and made an opening into it. The patient died in twenty-four hours. The third case I left entirely to nature, and the patient recovered with an artificial anus.

Dr. P. S. Conner, of Cincinnati: I have had three cases of gangrenous hernia, and have seen a fourth in the practice of Dr. Dandridge. The operation of intestinal anastomosis is valuable. It can be performed rapidly, it is simple, and establishes the continuity of the intestinal tract more perfectly than any other operation that has been suggested.

Dr. W. F. Peck, of Davenport: From my experience, I think that great benefit in the way of prevention would result from educating the subjects of this trouble in regard to the dangers of hernia and the way of reduction.

Dr. J. Ewing Mears, of Philadelphia: I have had two cases, one of umbilical hernia in which I made an artificial anus; the other of femoral hernia, where I performed resection and returned the intestine to the abdomen. Both resulted fatally inside of forty-eight hours. A surgeon of Vienna has suggested that in these cases the gangrenous intestine be withdrawn from the abdomen and held in place outside by a tampon of iodoform gauze. In this way the intestine can be kept under observation and treated as seems best.

Dr. W. W. Keen, of Philadelphia: I think that the introduction of the method of intestinal anastomosis by the bone plates of Senn or the catgut rings of Abbe is a great advance over former methods. The mortality following this method is greatly less than that following reunion of the ends of the bowel.

Dr. T. A. McGraw, of Detroit: I have heard nothing in regard to the pathological condition of the bowel above the seat of stricture. In some cases the bowel is healthy immediately above the point of strangulation, while in others the inflammatory process extends six to ten inches above the point of constriction. This must make a great difference as regards the results of operation.

Dr. A. Vanderveer, of Albany: Eleven years ago I saw a case of gangrenous inguinal hernia, but the condition was so bad that nothing was done. The patient died a few hours later. Two years ago I saw a similar case, except that the patient was younger and the collapse not so great. I opened freely and left it to nature. The man recovered with an artificial anus.

Dr. H. H. Mudd, of St. Louis: I think that gangrenous hernia is not so rare as seems to be the general impression, I can recall at least seven cases. Three of these cases occurred more than four years ago and all died. During the last four years I have operated on four cases, excising a portion of bowel, with recovery in one case.

Adjourned.

SECOND DAY, WEDNESDAY, MAY 15TH — MORNING SESSION.

DR. J. COLLINS WARREN, of Boston, read a paper entitled

THE EARLY DIAGNOSIS OF MORBID GROWTHS.

Reference was first made to the great desirability of some means of making an early diagnosis in cases of possible malignant disease. The attempt to make a microscopical examination of morbid growths before their removal dates back to the earliest period of microscopical histology. The pain and danger of inflammation attending the methods adopted led to their abandonment. Antiseptic surgery, however, now enables us to perform such an operation almost with absolute certainty of absence of inflammation. Local anæsthesia with ether spray or cocaine renders the exploration free from pain. The instrument which the author employs consists of a small cannula, sharpened at the end. The calibre of the instrument varies from two to five millimetres. The instrument is used by gently rotating the cannula between the fingers. After the instrument has penetrated the tumor to the desired depth, it is withdrawn a short distance, and then entered obliquely, so as to cut off the column of tissue. The piece removed may be as large as five millimetres in diameter and three centimetres in length, or even longer. The fragment can be at once examined by means of freezing microtome or placed in alcohol and hardened. The operation can readily be performed at the physician's office and immediate diagnosis made. Several cases were reported, illustrating the information obtained by the use of the cannula. The instrument has been used in over one hundred cases, with little or no discomfort to the patient and with satisfactory results. It has been used in abdominal tumors. It has been used in one or two growths involving the abdominal parietes and peritoneum, but not in deep-seated organs. The object of the author in bringing the results of his observations before the Association was to show that modern improvements have made an old and discarded method not only practicable but a valuable addition to our means of surgical diagnosis.

DISCUSSION.

DR. F. S. DENNIS, of New York: I wish to protest against reliance upon this instrument in the diagnosis of malignant disease. I have never found pathologists willing to base a diagnosis of malignant disease upon the shreds of tissue removed by such instruments. More reliance is to be placed upon the clinical features than upon the microscopical appearances. Among these are age, situation of the tumor, the macroscopic appearance, pain, cachexia, lymphatic enlargement, hereditary influence, and, finally, the use of the harpoon. While the harpoon or cannula is a useful adjuvant, we cannot rely upon it absolutely in making the diagnosis.

DR. P. S. CONNER, of Cincinnati: I think there is nothing more definitely established than the difficulty of relying absolutely upon the microscopical examination in cases of supposed malignant disease. It is a confirmatory testimony of great value. In the instrument presented we have an additional aid to our means of diagnosis. While the points presented by Dr. Dennis are valuable, they do not aid much in the early diagnosis.

DR. R. A. KINLOCH, of Charleston, N. C.: It is a well-established surgical principle that all tumors should be removed, so that the early diagnosis is perhaps not so essential. The question arises as to whether it would not be better to remove the tumor and make the diagnosis of its nature afterward.

DR. W. H. CARMALT, of New Haven: In carcinoma and sarcoma the clinical features are to my mind a great deal more important than anything we can obtain from the microscope. Microscopical examination of different parts of the same tumor may present different appearances. Another point in regard to the use of the cannula is the danger that the irritation excited by the instrument may convert a benign tumor into a malignant growth.

DR. M. H. RICHARDSON, of Boston: I have seen this instrument used in many cases without bad effect, and the microscopists consider that they derive valuable information from examination of the plugs of tissue removed. We cannot make a correct diagnosis in the earliest stage of maligant disease from the clinical evidence alone, and it seems to me that in the early diagnosis this instrument affords valuable aid.

DR. L. MCLANE TIFFANY, of Baltimore, then read a paper entitled

FREE DIVISION OF THE CAPSULE OF THE KIDNEYS FOR THE RELIEF OF NEPHRALGIA.

Four years ago the author had suggested the use of incision of the capsule of the kidney in the treatment of nephralgia. The patient, a woman, aged forty-nine, white, married. Had had gonorrhœa and syphilis. She had had abscess of the pelvis opening by the vagina, the discharge continuing for two years. Three years ago she experienced in the right loin sudden severe pain lasting for a moment. It was supposed to be due to passage of a kidney stone. The attacks recurred at irregular intervals, the periods becoming progressively shorter and the pain more intense. No calculi had ever been voided. Blood had been seen at rare intervals. The pain always began in the right loin midway between the pelvis and the ribs. It then extended toward the middle line of the body and down to the bladder and groin on the right side. Exertion was apt to induce it. Pressure over the right kidney caused acute pain, but no tumor could be made out. The urine was moderately acid, sp. gr. 1.022, contained pus-cells and a few red-blood disks. There was no rise of temperature during the attacks.

The operation was performed, January 12, 1889. The kidney when exposed moved freely during respiration. A deep stellate scar existed in the kidney, two inches from the lower end. No other abnormality was discovered. A sound was passed into the pelvis and a systematic exploration made, but no stone was detected. The capsule was then freely slit open for three inches. The edges of the cut gaped widely. The wound was then closed and an aseptic dressing applied. No urine passed by the lumbar wound. This soon healed and since the operation, a period of four months, there have been no attacks of nephralgia.

DISCUSSION.

DR. THEODORE A. MCGRAW, of Detroit: Three months ago, I operated on a woman on the supposition that there was a renal calculus. None was found, but the capsule was freely slit and since the operation there has been no return of pain.

DR. LANGE, of New York: In one case of severe pain recurring at irregular intervals, I operated with the expectation of finding a stone in the kidney, but none could be detected. I then proceeded in the manner described by the reader. The patient remained free from pain for three or four months. The attacks then reappeared.

DR. W. W. KEEN, of Philadelphia: I would like to refer to one source of error in the diagnosis of renal calculi which has not been mentioned. I recently operated on a case of tumor of kidney in which when the needle was passed into the substance of the organ it gave a distinct impression of coming in contact with a stone. The tumor was malignant and so adherent that it could not be removed. Subsequent examination showed that there was no calculus and that the needle must have come in contact with a calcareous vessel, of which there were several, or a mass of calcareous matter which was present.

DR. JOHN HOMANS, of Boston: I recently operated in a case in which there was a large swelling in the perineum in a boy aged fifteen. I removed by perineal section thirteen stones from the urethra. The urethra would admit my forefinger. There was also a swelling in the loin

which did not disappear after the operation. Three weeks latter I opened the kidney through the right loin. I found a considerable quantity of pus but could detect no stone, although I am not sure that a stone may not be present.

The next paper, read by DR. J. M. BARTON, of Philadelphia, was entitled

DIGITAL DIVULSION OF THE PYLORUS FOR CICATRICIAL STENOSIS.

Digital divulsion of the pylorus for cicatricial stenosis, as first practised by Professor Loreta, of Bologna, Italy, in 1882, has scarcely received the attention which I think it deserves anywhere except in Italy. The mortality from the twenty-five operations which I have succeeded in collecting is not great when we consider that every successful case is a patient rescued from certain and by no means distant death, and this mortality is already decreasing.

The cases in which the operation would be of service are not so very rare. When searching the journals for records of such operations I found the reports of the presentation of many specimens of cicatricial stenosis of the pylorus to various pathological societies. My own experience has been limited to two operations. Even the first, though it proved fatal on the fourth day, encouraged me to operate again, as I was fully satisfied that had it been performed earlier, when the patient was stronger, there was no reason why it should not have been successful.

My second case has the following history: Mrs. G——, aged forty-eight, a patient of Dr. Adams, of Vineland, N. J., was first seen by me at her home near Vineland, in December, 1888. For convenience of study and operation I admitted her to Jefferson College Hospital in January, 1889. During 1884, 1885, and 1886 she had suffered from gastric ulcer; she had pain and vomiting immediately after eating, the vomiting occurring as often as six times in the twenty-four hours; she lost greatly in weight and had two severe hemorrhages. In 1887 all of the symptoms left her, and for the greater part of the year she enjoyed excellent health, weighing in January, 1888, one hundred and forty-three pouuds, which was more than she had ever weighed in all her life. During 1888 she became very ill with symptoms of pyloric obstruction and lost flesh rapidly, weighing after her admission to the hospital (January, 1889) only ninety-three and one-half pounds. She then vomited but once in twenty-four or forty-eight hours. This occurred when she laid down at night and was not accompanied by nausea. It was usually from one and a half to two quarts in quantity and measured nearly and sometimes quite as much as all the nourishment taken since the preceding act of vomiting twenty-four hours before. Many articles taken during the day could be recognized; indeed, she stated that she had occasionally been able to recognize articles eaten as long as two weeks before. As she took her meals she felt that the stomach was becoming more and more distended and when she laid down at night, gravity brought the contents of her stomach into her throat and they were then vomited. Her bowels were obstinately constipated, acting only once in twelve or fourteen days, and then only after frequently repeated large injections, purgatives administered by the mouth producing no effect. She had lately been able to occasionally feel a small tumor about the size of a hazel nut, two inches to the right of the umbilicus, and situated quite deeply. Her stomach was greatly enlarged; distended by the carbonic acid gas developed from half of a soda powder it reached as low as the umbilicus, and as far as the small tumor, though we could not say that the tumor was connected with the stomach.

The vomited matters separated themselves into the usual three layers, the middle one being quite clear; they were nearly free from undigested food and not offensive; free hydrochloric acid, though searched for, was not found.

The operation was performed in the presence of the class of Jefferson Medical College, February 16, 1889. The surface of the abdomen had been prepared the day before, the mercurial dressing being still on when the patient was brought into the amphitheatre. Her stomach had been washed out on the morning of operation with a solution of biborate of soda. This had been repeated until the fluid returned quite clear. Chloroform was used as the anæsthetic in preference to ether, as being less apt to be followed by vomiting. The hands and instruments having been prepared with antiseptic solutions, I made a median incision through the skin, about four inches long, terminating at the umbilicus. The peritoneal incision, however, was only three inches in length. There was but little bleeding, and it was readily controlled by clamp forceps.

The dilated stomach was found directly beneath the incision. The juncture of the stomach and duodenum, even from the outside, was markedly contrasted and irregular on its surface. There were no adhesions and there was no tumor. The tumor was found to be a hard scybalous mass in the ascending colon which also contained quite a number of smaller masses of hardened fæces. As the wall of the stomach three inches from the pylorus felt quite healthy, I folded it transversely, midway between the greater and lesser curvatures, and with a pair of sharp scissors made an incision between one and a half and two inches in length. There was no bleeding requiring attention. I introduced my index finger through this incision, and felt the pylorus contracted to about the size of a No. 10 French catheter; its margins were quite hard and fibrous. As the fingers would not enter, the blades of a small uterine dilator were guided by the finger into the contracted pylorus, which was then readily dilated until it admitted the index finger. With the aid of a pair of œsophageal forceps it was still further dilated until both the index and middle fingers were admitted. The two fingers were then separated about half an inch, when I ceased, feeling that further effort would probably rupture the mucous membrane. This dilatation gave to the pylorus a circumference of four and one-half inches.

The mucous membrane of the stomach at the point of incision was brought together by a continuous silk suture, and the serous coat by a continuous Lembert suture, also of fine silk, carried in an ordinary sewing needle. This suture was introduced deeply into the muscular coat in order to obtain a firm hold, even then it tore out at one or two points, requiring an interrupted suture to be used at those places. When the finger was first introduced into the stomach it caused some retching, forcing most of the stomach out of the wound, where it was kept during the subsequent manipulations. After the wound in the stomach was closed, the organ was carefully sponged and restored to the abdominal cavity. The abdominal wound was then closed and dressed in the usual manner.

The patient vomited about four ounces of blood half an hour after the operation, but there has been no nausea and no vomiting since. She was nourished exclusively by the rectum until the fourth day. From that time until the fourteenth day she was fed upon peptonized milk and animal broths. After the seventh day she took from forty-eight to sixty ounces of liquid nourishment in the twenty-four hours. Some solid food was given on the tenth day, and after the fourteenth day she was fed upon a carefully selected solid diet. On the thirtieth day after the operation she was able to eat eggs, mutton chops, oysters, beef, chicken, lamb, potatoes, cream toast, bread and butter, milk, and coffee. Her temperature has never been over 99° F., nor under 98° F. since the operation. Her bowels act naturally every day. The abdominal stitches were removed on the ninth day. On February 8th, before the operation, she weighed ninety-three and a half pounds; March 25th she weighed one hundred and ten pounds; April 15th, one hundred and eighteen pounds, and April 27th, one hundred and twenty-two pounds. She was able to leave the hospital April 10th. She had no pain at any time and required no anodynes.

* In a letter to Dr. Harris, Loreta stated that to November 30, 1888, he had had 9 cases, of which 3 were cured and 4 died, 3 from shock and 1 from hemorrhage.

I have succeeded in collecting twenty-five published operations, many or these are by Professor Loreta. I had hoped to have obtained the result in all his cases, but Dr. Peruzzi, his chief assistant, replies to a letter of inquiry that the Professor has performed in all about thirty operations, and that at least six more have been performed by other Italian surgeons. They were all successful when the diagnosis was correct. This would make the total number of operations about 43. The 25 operations included in my list were performed on 24 patients, one patient having been operated on twice successfully by Professor Loreta. From the 25 operations there were 15 recoveries and 10 deaths, making a mortality rate of forty per cent. Of the 10 deaths, 6 were due to shock, 2 to hemorrhage, 1 to tetanus, and 1 to suppression of urine.

The large mortality from shock in an abdominal section performed in from half an hour to an hour is probably due to the fact that in this, as in most new surgical procedures, the operation is postponed too long. The mortality is already decreasing. Of the first 12 cases reported 6 recovered and 6 died, while of the last 12, 9 recovered and 3 died. This mortality can perhaps be still further lessened by earlier diagnosis and operation, and by such methods of operation as are most quickly performed and accompanied by the minimum loss of blood.

DIAGNOSIS.

The diagnosis can be conveniently divided into two parts: 1, To determine the existence of pyloric obstruction; and 2, to differentiate between obstruction caused by cancer and that caused by cicatricial stenosis. But few of the reported cases have such a typical history as the one I have related. The co-existence of dyspeptic symptoms, or of some still open ulcers, complicated the diagnosis in most of the cases. I should regard as of little value some of the symptoms upon which much stress has been laid. The material vomited in some cases consisted of partly digested food, in some it was wholly undigested and offensive, while in others it consisted of well-elaborated chyme. The character of the material indicates the health and physiological activity of the stomach, but throws little light upon the condition of the pylorus. In some cases sarcinæ were present, but in many they were absent. The same may be said of starch granules, of needles of the fatty acids, of free hydrochloric acid, of pain, and of other dyspeptic symptoms which have usually existed for many years before the symptoms of obstruction occurred.

The following symptoms I would consider of value: 1, A greatly dilated stomach; 2, the vomiting of from one to two quarts of material at one time; 3, the recognition in the vomited matter of articles that have been taken many hours, days, or weeks before; 4, when the act of vomiting is peformed with great ease, without nausea, and the appetite is good immediately afterward; 5, obstinate constipation; 6, the non-effect of ordinary purgatives; 7, a preceding history of gastric ulcer of several years' duration and temporary improvement followed by simple obstructive vomiting of well-elaborated chyme many hours after taking food. This typical history occurred but twice among the twenty-four cases. Where the symptoms are obscure great reliance may be placed upon the detection of a decidedly enlarged stomach, as this is rare except as a result of mechanical obstruction of the pylorus.

The mere presence of tumor is almost without value in the differential diagnosis between cancer and stenosis. In the 24 cases tumor was present in 7, absent in 4, not noted in 13. A rapidly growing nodulated tumor low down in the abdomen is probably malignant. A poorly defined tumor, not increasing in size, high in the abdominal cavity, is probably non-malignant. The average duration of cancer of the pylorus is one year (Brinton), the maximum duration three years (Bartholow). The average duration of the gastric symptoms in 13 of the 24 cases in which this is noted was eleven years. The history of temporary improvement is against malignant disease. In the later stages of cancer the obstruction is often removed by ulceration, and diarrhœa occurs. In the later stages of ulcer the obstruction increases and the stenosis is more obstinate.

THE ABDOMINAL INCISION.

In all of the reported cases but two methods of opening the abdomen have been used. One by an incision running from one inch below the ensiform cartilage to the extremity of the ninth rib on the right side, a distance of about six inches; the other by an incision in the median line between the ensiform cartilage and umbilicus and from three to six inches in length. The first method was used by Loreta in his earlier cases but he now uses the latter exclusively.

The stomach wound should be made far enough from the pylorus to be in healthy tissue. If some inches from the pylorus, it will be outside the zone of inflammation

following the dilatation. Experimenting upon cadavers, I found that separation of my fingers more than an inch caused rupture of the mucous membrane.

The stomach-wound has been closed in many ways and all did well. In no case was there the slightest leakage. No case suffered from peritonitis and in none was the stomach-wound the cause of death. I would suggest that probably the best method would be a continuous suture of catgut to the mucous membrane and the suture of Appolito to the peritoneum.

DIET.

In some of the reported cases food has been given as early as a few hours after the operation without injury. I delayed until the fourth day, although I see no reason why food should not be given earlier. Peptonized milk, animal broths, diluted wines, and the yolks of eggs would be the best articles, according to the condition of the stomach prior to operation. Rectal alimentation will be required until sufficient food can be given by the mouth. Solid food has rarely been given before the tenth day and then sparingly.

PERMANENCY OF CURE.

Recontraction of the cicatricial tissue would naturally be feared, but Loreta, in January, 1885, nearly three years after his first operation, writes: "I have now operated on six cases; they all have recovered and all remain well up to the present time." Haggard in 1888 reports that the case he operated on two years before was "still perfectly well, no vomiting, dilatation of stomach less, and she has recently married." Peruzzi in his letter to me, March 22, 1889, states that he knows of only one relapse among the thirty cases upon which Professor Loreta has operated. This patient was reoperated upon, recovered, and remained well.

In four of the fatal cases included in the list the obstruction was valvular, due to irregular contraction of the walls of the stomach. In another case, not included in the list, as the stomach was not opened, the valvular obstruction was caused by distortion produced by external adhesions. These were divided and the patient made a good recovery. In another case, not included in the list, the operator, recognizing that he had badly ruptured the mucous membrane while stretching the pylorus, immediately performed pylorectomy, with recovery of the patient. In another case the obstruction was caused by an adherent pancreas. The cause of the adhesion was an ulcer starting in the posterior wall of the stomach and penetrating the pancreas. In this case incision about two inches in length was made from stomach to duodenum, passing through the pylorus. The two extremities of the wound were brought in contact and the wound sewn up at right angles to its position when made. When completed, it was parallel to the long axis of the body. This patient recovered after a serious illness.

DISCUSSION.

Dr. R. A. Kinloch, of Charleston, S. C.: I have no personal experience with this operation. We must accept the testimony of reliable men, but I cannot understand how an organic stenosis of the pylorus is cured by a single dilatation. This is not the case with organic stenosis in other parts, as the rectum and the œsophagus. I am inclined to believe that where the benefit has continued for any length of time the organic change has been slight. I can understand how benefit would be expected if the wound were kept open and the stricture systematically dilated.

Dr. M. H. Richardson, of Boston: The mortality of gastrotomy as a primary operation is extremely small. I have also found from sixty dissections that the longitudinal incision between the greater and lesser curvatures made the best incision for reaching either the pylorus or the cardiac extremity of the stomach. The shortest incision was one inch but the incision usually required was two or three inches.

Dr. J. Ewing Mears, of Philadelphia: While it may not be easy to explain the results obtained by digital divulsion of the pylorus, there can be no question as to the beneficial results. The evidence of reliable operators certainly indicates that it is a proper operation and attended with successful results. This operation should always be performed in preference to pylorectomy.

Adjourned.

Correspondence.

INHALATIONS OF CHLOROFORM IN PHTHISIS.

To the Editor of The Medical Record.

Sir: In your issue of April 27th, page 465, "News of the Week," I notice the following: "Inhalations of Chloroform (Clemens) is among the latest specifics for the cure of phthisis pulmonalis."

Scientifically considered, as well as from a practical application, chloroform inhalations should prove *the* remedy for the *staying*, if not for the cure of pulmonary phthisis. Attending a former faithful servant, Paul P——, for laryngeal phthisis, following chronic pulmonary phthisis, last fall, I was driven to the wall with my remedies by the severity of the case—the pain, particularly, becoming so severe that deglutition became almost impossible. I had read the notice, in several journals, of the antiseptic powers of *chloroform water* in the earlier part of 1888, and I presume this created a chain of thought the final link of which was suddenly furnished on November 3, 1888, on my way home from a visit to Paul P——, by the spontaneous conclusion that inhalations of chloroform as a remedy for phthisis pulmonum, was the ideal therapeutic means of combating the disease, if the reasoning that this disease owes its origin and progress to the presence and work of Koch's bacillus is correct.

On my return to my home I at once informed my wife, who administers chloroform for me at all times, from the operation of ovariotomy to the lancing of a felon, and also my secretary, Mrs. Kathrine DuBois, of my conclusions. That same afternoon I gave chloroform inhalations for the first time as a remedy for phthisis, and, to my surprise, my patient did not only enjoy the euthanasia, which even one-half grain doses of morphine and five per cent. solutions of cocaine had denied him, but he also slowly but surely revived to such an extent that he was enabled to partake of food abundantly, in consequence of which he soon left the bed; however, to succumb eventually to the disease, a very rapid acute miliary tuberculosis.

Cases of phthisis pulmonum are not very frequent in Nebraska, and only one case out of four treated hitherto presented itself which gave reasonable assurance that any kind of remedy might prove beneficial. A typical case, D. H——, from Massachusetts, came to me, January 7, 1889, and was treated until February 16th by inhalations of chloroform, the vapors of which were saturated with turpentine and balsam of Peru, all of this being forced into the lungs by compressed oxygen gas. His wife writes me, under date of March 31, 1889: "Mr. H—— has been out every day since our return either walking or riding, some days both; last Thursday worked three hours at carpentry; seemed tired but not exhausted. Yesterday helped me in papering a room an hour or more, besides walking down town twice, a distance as long as from your house to the post-office (about a quarter of a mile), and now contemplates painting a room."

At this writing the patient is steadily improving, and if it is noted that he could scarcely be out of bed when he came to me, the conclusion is justifiable that he has been reclaimed by the means employed.

I will not enter into details further than to say that

since the third day of November last I have diligently searched for information regarding the inhalation of chloroform as a remedial agent, and found it only alluded to *once*—in Dr. Wesener's paper in the fourth volume of the *Journal of Bacteriology*, entitled "The Antiparasitic Treatment of Pulmonary Consumption," page 797. I read (translated): "Also inhalations of which he (S. Solis-Cohen) deems useful, are creasote, æthyljodid, terebin, turpentine oil, tincture of benzol, thymol, and chloroform."

The learned author of the paper alluded to, by my request, sent the same to me. It is a reprint from the "Transactions of the Medical Society of the State of Pennsylvania," vol. xix. On page 11 he says: "Chloroform finds indications as a sedative to troublesome cough, and as a mitigant of the sharpness of some specimens of terebene." You will find in this quotation not the slightest hint of the use of chloroform as a remedial agent for the cure of consumption.

The first and only allusion to this use of chloroform comes to me in the quotation from THE MEDICAL RECORD, heading these lines. You will fully appreciate my desire to be put into the possession of Dr. Clemens' paper; aiding me in this, you will put me under great obligations.

Very sincerely yours,

A. G. MANSFELDE, M.D.

QUALITY HILL, ASHLAND, NEB., April 30, 1889.

"WANTS TO KNOW IF CHRONIC NASO-PHARYNGEAL CATARRH CAN BE CURED."

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The answer to this question, which I find propounded by G. P. H. in THE MEDICAL RECORD of May 18th, can be made only in the same way that any similar question can be answered. Suppose anyone were to ask: "Can chronic nephritis, or chronic pneumonia, or chronic pleurisy be cured?" How might we reply to the query intelligently?

We would say it will depend upon the causation, duration, and complicating conditions present in the disease referred to. Certainly no sensible practitioner of medicine can be expected to furnish a panacea or a pet formula for the cure of a symptom in manifold pathological changes. Naso-pharyngeal catarrh, even "in subjects of the nervous and sanguino-nervous temperaments," may be allied with every constitutional dyscrasia, a result of some well-defined local change in the nasal passages, dependent upon disease in almost every remote organ, kept up by habits, professional pursuits, or immediate surroundings. It is time our notions in regard to the judicious handling of diseases of mucous membranes were readjusted. Our mental vision seems frequently obscured in regard to facts of daily observation. It will requre a moderate return to the wisdom of those who have preceded us to appreciate that local treatment alone for chronic naso pharyngeal catarrh is irrational and correspondingly ineffective.

B. R.

IS THIS TRUE?—A correspondent writes: "It may be of interest to you and to the readers of THE RECORD to know that while the 'Code' of the American Medical Association is maintained as a bar against the Medical Society of the State of New York and its co-operative societies, it appears to be waived, at the discretion of the Chairman of Sections and of the Chairman of the Committee of Arrangements, in favor of non-professionals (of medicine) who are ambitious to use the Association for ulterior ends."

STOMACH VERTIGO is said by M. Bovet to be due to auto-intoxication. He has found in the urine and gas of the stomach and intestines, after vertiginous attacks, cyanides and sulphuric acid sufficient, he thinks, to have been the cause of the vertigo.

Army News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 12 to May 18, 1889.

By direction of the Acting Secretary of War, a board of medical officers, to consist of Lieutenant-Colonel ANTHONY HEGER, Surgeon; Captain F. C. AINSWORTH, Assistant Surgeon; and Captain JOHN O. SKINNER, Assistant Surgeon, will assemble at the U. S. Military Academy, West Point, N. Y., on June 1, 1889, to examine into the physical qualification of candidates for admission, and members of the graduating class. Par. 9, S. O. 108, A. G. O., May 10, 1889.

By direction of the Acting Secretary of War, the following named officers are detailed to represent the Medical Department of the Army at the annual meeting of the American Medical Association, to be held at Newport, R. I., on June 25, 1889: Major SAMUEL M. HORTON, Major JOHN S. BILLINGS, and Major CHARLES SMART, Surgeons. Par. 15, S. O. 110, A. G. O., May 13, 1889.

GORGAS, WILL'AM C., Captain and Assistant Surgeon, Will accompany the command from Fort Barrancas, Fla., and proceed with Battery H, 2d Artillery, to Fort Adams, R. I., to return to his proper station on completion of this duty. Par. 5, S. 108, Headquarters Division of the Atlantic, Governor's Island, N. Y. City, May 13, 1889.

GORGAS, WILLIAM C., Captain and Assistant Surgeon, now on duty at Fort Barrancas, Fla., will report in person to the Commanding General, Department of the Missouri, for temporary duty with troops in the field. Par. 1, S. O. 112, A. G. O., Washington, May 15, 1889.

GORGAS, WILLIAM C., Captain and Assistant Surgeon. Ordered to proceed at once and to report to the Commanding General, Department of the Missouri, for temporary duty in the field.

EKERT, R. G., Captain and Assistant Surgeon. By direction of the Acting Secretary of War, leave of absence for six months, on surgeon's certificate of disability, is granted. Par. 5, S. O. 109, A. G. O., May 11, 1889.

MOSELEY, E. B., Captain and Assistant Surgeon. By direction of the Acting Secretary of War, leave of absence for six months, on surgeon's certificate of disability, is granted. Par. 6, S. O. 109, A. G. O., May 11, 1889.

TESSON, LOUIS S., Captain and Assistant Surgeon. By direction of the Acting Secretary of War, is relieved from duty at Watervliet Arsenal, N. Y., and ordered to Fort Sidney, Neb. Par. 9, S. O. 109, A. G. O., May 11, 1889.

DAVIS, WILLIAM B., Captain and Assistant Surgeon. By direction of the Acting Secretary of War, the ordinary leave of absence granted him in Special Orders No. 232, October 5, 1888, is extended six months on surgeon's certificate of disability. Par. 20, S. O. 108, A. G. O., May 10, 1889.

KEAN, JEFFERSON R., First Lieutenant and Assistant Surgeon (Fort Robinson, Neb.). Leave of absence for one month, to take effect between June 1 and 15, 1889, is hereby granted, with permission to apply at Headquarters Division of the Missouri for an extension of fifteen days. Par. 2, S. O. 48, Headquarters Department of the Platte, May 13, 1889.

THE MANAGEMENT OF LABOR IN THE VIENNA HOSPITAL.—In a case of labor the following procedures are adopted: As the head comes to the vulva the parts are irrigated with corrosive sublimate solution, 1 : 5,000. Again, after the child is born, and after the placenta has been expressed, the vagina is again thoroughly washed out with the same solution; then a plug of iodoform and cocoa-butter (two per cent. iodoform) is introduced into the cervical canal, iodoform dusted over the external parts, iodoform gauze applied to the vulva, and a bandage over all and about the body.—*Occidental Medical Times.*

THE CARE OF THE TEETH, FROM A MEDICAL PRACTITIONER'S STAND-POINT.[1]

BY SAMUEL SEXTON, M.D.,

NEW YORK.

I SHALL confine my remarks to quite a limited consideration of dentition, caries of the teeth, and some of the neuroses resulting therefrom.

Though this subject has an extensive and valuable literature of its own, particularly in respect to the anatomy and pathology of the teeth, yet a wide field remains, in a medical point of view, for further observation and research, especially in respect to the treatment of affections influenced by dental irritation coming under the physician's care.

Were rational methods of research—such as have characterized the exact study of diseases of that group of special sense-organs comprising the ear, nose, and eye, and contributing so greatly to the success of specialism—brought to bear throughout the field of oral surgery, the marked indifference of physicians toward this specialty would soon cease to exist. There is every reason a more general knowledge of the teeth should prevail among medical men, when the well-known sympathy between them and their highly specialized neighbors is considered, since neither one of these organs, including the teeth themselves, can be long affected without disturbing the equilibrium of the nervous distribution about the head. It is well known that these different organs, when diseased, have a more or less retroactive influence on each other; the moment one of them is ailing, its morbid influences are propagated to the rest, though not necessarily affecting them all in the same degree. The most superficial knowledge, indeed, of the *modus operandi* of the complex nervous network involved, shows how puzzling under treatment for many of the diseases to which they are subject the behavior of the ear, nose, and eye at times must be, without taking into consideration the influence of diseased teeth. Of course in health these highly organized neighbors maintain an independent and separate existence, so to speak, their intimate sympathetic relationship scarcely manifesting itself perceptibly. Under certain conditions of the system, however, these organs become strikingly susceptible to disturbing influences, and so far as my own experience goes, from no cause more frequently than dental irritation.

There are certain periods in life when dental disturbances are most marked, and at such times the trouble is emphasized in run-down subjects; these periods are the first dentition of infancy, the completion of the second dentition at puberty, and the eruption of the wisdom teeth. During the first three years of childhood, while the first twenty teeth, comprising the first set, are coming, more or less irritation from soreness of the gums is generally experienced, and often the suffering from pain and sympathetic disturbance is very great.[2]

Dentition is spoken of as a physiological process, but nature very often dispenses rather torment than pleasure during the active stages of dental evolution. The clumsy work of the blunt tooth crown, slowly and painfully crowding its way through the tough gum tissue is a severe draft on the infant's store of nervous energy, and in many cases it can but be a source of wonder that they survive the struggle. From the irritability due to loss of sleep, headache, gastric disturbance, etc., many infants are kept in a run-down state all the time, and are, therefore, exceedingly susceptible to head catarrhs, and consequent aural, nasal, and ophthalmic complications, whose management is the more difficult, inasmuch as this causative influence, often the principal one, uninterruptedly continues.

One is surprised at the reluctance so often manifested in acknowledging the vast importance of dentition as a factor in infantile disorders, since instances are by no means infrequent where the trauma, due to the contusion of every tooth coming through the gums, is accompanied by convulsions or an exacerbation of the ear, nose, or eye trouble to which the process may happen to be particularly obnoxious. Fortunately, however, the cruel punishment meted out along with the first instalment of dental fixtures is followed by a period of comparative rest and recuperation from the exhaustive labor of dentition, lasting until about the sixth year.

During the interregnum between first and second dentition, or at any time after they are cut, the first teeth may decay prematurely as a result of malnutrition; or tartar may form on them. If catarrh of the gums now occurs, with suppuration of the socket and periostitis of the alveolar processes, besides the distressing oral irritation ensuing, some of the teeth may be lost.

Second dentition, often beginning at the end of the fifth year, but usually during the sixth year, is delayed a year or two in some feeble children backward in their development, though, before coming through, the site of the two lower six-year molars may long be seen beneath the gum, as indicated by a well-marked prominence.

Children may not suffer pain from the permanent teeth while pushing their way underneath the temporary set, though they frequently become very nervous indeed. Deciduous teeth now have their nutrition cut off, become gradually loosened by absorption, and are pushed out of the way as so much rubbish. In children having narrow jaws, the teeth, coming in rapidly, are liable to be crowded out of place. In ill-nourished children early decay of the teeth is to be feared. Where such mishaps take place, and fragments of shedding teeth remain attached to the gums, an appalling amount of irritation is set up in the mouth. Second dentition is often a severe ordeal, as may be surmised, and if children are badly fed and clad, and overworked mentally or physically, they are liable to give way under the strain. The exanthemata are illy borne during difficult dentition, and the teeth afterward give evidence of malnutrition, the arrest of development leaving various tracings upon them. The shape and strength of the teeth are often thus modified by constitutional influences during their growth. A number of these defects are known to occur with considerable uniformity, and have received appropriate names indicating their anatomical appearance. The writer has, however, looked in vain for characteristically marked teeth which might be traced to any particular disease, such as have been described by

FIG. 1.—"Hutchinson's" teeth.

[1] Read before the Practitioners' Society of New York, May 3, 1889.

[2] Persons interested in the study of the anomalies and diseases of the teeth, at all ages, in man, will find a classified collection, taken from cases in the author's aural practice, in the Army Medical Museum, Washington. The cases are represented in plaster casts which were made by the Messrs. Stebbins, dentists, of this city. Dr. Billings has had a descriptive catalogue prepared, and the collection is in a convenient place for study.

Hutchinson (Fig. 1), for example, as due to syphilis. While children subjected to the cramming process of our public schools have execrably bad teeth, it is alleged that among deaf children and others of slow mental development the contrary holds good.

The cutting of the four second molar teeth takes place about the twelfth year, and concludes the second dentition, excepting the wisdom teeth, which, on account of its importance, I have here regarded as a third process.

Until all of them are entirely through the gums the teeth of children should be kept under observation, since many nervous affections are due to the physiological disturbances they give rise to, and being unattended by pain are liable to be overlooked.

The *dens sapientiæ*, or third molar teeth, due about the seventeenth year, are often several years behind their time. In the lower jaw they are in erupting prone to take a header, so to speak, and land against the second molar, already firmly implanted in its place. The futile efforts, after a false start, to crowd into line with the other teeth is sometimes attended with agonizing pains, and is not always successful.

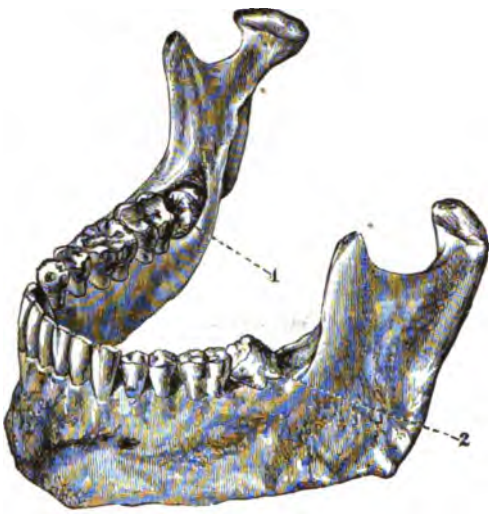

FIG. 2.

This is well shown in Fig. 2[1] (from a specimen in the author's possession). The right wisdom tooth, 1, is wedged in between the ramus or upright portion of the jaw and the second molar tooth; it has not, as yet, been able to leave its socket and cut through the gum. As the tooth is urged onward in the effort to erupt, it is forced against the sensitive root of the neighboring tooth, the pressure giving rise to much irritation. The fully erupted left wisdom tooth, 2, is inclined toward the first molar; the second molar on this side having been lost, room was afforded this tooth to cut through the gum.

Sometimes the irritation goes on for years, until nature seems to exhaust her expulsive forces without completing the process of eruption; pains may or may not be experienced; sometimes they seem to shoot from the tooth to the ear. Through nervous sympathy the ears are very often affected. The two upper wisdom teeth usually erupt a short interval after the two lower, and are cut with less difficulty; they often keep well out of view, presenting themselves to the buccal cavity.

Since these molars seldom occupy their normal place in the jaws they are comparatively useless, and it is generally believed that their extraction is no loss. But whether the pains of eruption are great or absent altogether, the ear, nose, and tonsils often suffer very much from the long-continued irritation through nervous sympathy. Sometimes a flap of the gum remains over the second and third molar teeth for a considerable time after they are cut, indeed until they assume their proper position on a level with the other teeth. This flap of hard tissue remains attached to the gum posteriorly, and is kept in an irritable condition by the mastication of food. The removal of these inconvenient flaps may be accomplished with the knife, shown in Fig. 3. Dr. Frank Abbott has devised a cutting instrument, worked with forceps-like handles, having a strong biting apparatus, into which the flap may be pressed for removal.

FIG. 3.

Caries of the teeth, owing to their insensibility and density, is a slow and insidious process, unless the teeth are abnormally soft. The patient may not be aware of any disease until either the central pulp or periosteal covering becomes inflamed and sensitive to thermic changes, produced by hot or cold fluids and the like. Susceptible persons, as is known, often experience excruciating pain, since both the pulp and periosteum are well supplied with sensitive nerves. If caries progresses too far before the diseased portion is removed, and the cavity stopped, sooner or later the inflammatory process extends itself from the pulp-chamber downward through the fangs into the cellular tissue underneath, where an abscess is liable to form. The purulent matter may, whether partially encysted or not, escape either through the hollow crown or find an outlet alongside the root. The former, however, is often prevented by the minuteness of the canal of the fang, or by the closing up of the crown cavity with food or by a filling. An abscess at the apical outlet of the fang may remain for a long time, the purulent matter finding an outlet into the mouth in the manner above described, causing foul breath, and sometimes a very disagreeable taste.

Drainage through the gum is probably facilitated when the tooth has been partially denuded by detachment of the periosteum. Some of the products of inflammation are, probably, taken up into the system directly from the abscess by absorption. So long as matter escapes one way or the other, the patient may experience but little pain or other inconvenience. Should the drainage be arrested from any cause, for example, as from taking cold after the crown has been stopped, or filled with impacted food, pain and swelling of the jaw takes place, Everyone is familiar with the comically swollen face so often seen in connection with a "gumboil," as the abscess accompanying the exacerbation is popularly called. It is a misnomer to designate these teeth as absolutely "dead" so long as any nutrition is derived from the periosteum of the alveolus, though the perhaps equally important source of vitality, namely, the pulp, may be wholly wanting. The ultimate career of carious teeth, where the pulp is absent, depends largely upon the state of the periosteal envelope; this, being very tenacious of vitality, may aid in retaining the tooth a long time. In many instances, however, the painfulness of exacerbations, after a tooth has been stopped, is unendurable, and the offender is extracted. In some vigorous persons a "dead" tooth may remain in the jaws, even after being filled, without perceptible irritation for a long time. But in most persons, especially those who have become run down, there is more or less nervous irritation, often without any perceptible disturbance in the tooth itself, which, together with the effects produced by a deep abscess in the gums, very decidedly affects the health in one way or another. Moreover, as the death of the tooth becomes more complete its position in the jaw is similar to the sequestræ of bone—it is more or less of a foreign body. On the removal of pulpless teeth, which have been filled for some time, a surprising quantity of fetid matter and highly offensive gas often escapes from the pus cavity.

Destructive inflammation sometimes is set up in the pulp of a tooth by the concussion of a fall or a blow, the tooth afterward becoming more or less dark in color, as in instances where the loss of the pulp occurs in consequence of caries.

[1] From the Ear and its Diseases: Sexton. William Wood & Co. 1888.

Carious teeth are not only often sensitive to thermic changes, as has been stated, but they may be tender to the impact of mastication or other force applied to them. When metal fillings are not well borne in the cavities of sensitive teeth, because of their readiness to transmit impressions of hot and cold, the pulp often becomes so painful that dentists destroy it entirely, afterward filling the pulp chamber and canals of the fangs with substances more or less indestructible. In this procedure the cavity of the tooth is made as free of carious tissues as possible before it is filled.

These teeth are tolerated in the jaws, after they have been stopped up, for a longer or shorter time. They are usually sensitive in some degree, as morbid action scarcely ever ceases entirely. Suppuration occurs in a very considerable number of instances, and pain is experienced in consequence of the pressure of retained secretions. Relief usually follows removal of the filling; if this is delayed a gumboil is established with an outlet on either the buccal or palatal surface of the gum, but most frequently in the former situation. The minute opening of these sinuses, to the inexperienced, is often difficult to find, and hence the existence of a suppurating cavity, consequent on a gumboil, is not always suspected, but may exist for years without discovery unless the outlet becomes obstructed. The roots of the teeth underneath the antrum of Highmore impinge closely upon this cavity of the upper jaw, and alveolar abscesses sometimes find an outlet into it; the purulent matter finally escaping through the nose.

The question of retaining these so-called dead teeth in the jaws is one to which I have been obliged to give much attention, since a very considerable number of persons coming to me with aural affections have nervous troubles associated therewith which cannot be successfully treated until the affected teeth are removed. I have found that the irritation propagated from diseased teeth, especially those filled after destruction of the pulp, has very often delayed or even prevented recovery. After the removal of such teeth recovery is often very rapid. Much has been said about the harmlessness of keeping diseased teeth in the jaws, but we must remember that the practice is never a safe one, since it ignores the very first principle of surgery, namely, the maintenance of drainage. Moreover, it is not possible to thoroughly clean out the canal cavity of most carious teeth, and even if this were accomplished, it would not prevent further necrotic action going on in the pulp-chamber, canal of the roots, or at the apical outlet under favoring circumstances, since the main source of nutrition is cut off from these parts. The filling material is sometimes pushed through the canal of the root into the tissues beyond. A case of this kind once came to me where the gold used in filling had thus kept up an irritation for more than ten years, which, though not appreciable locally, caused neuralgic pains in the head. Entire relief followed removal of the tooth which I now exhibit (see Fig. 4), that the members of the Society may examine for themselves. It would seem that such accidents as the above could not always be avoided, since the dentist must carry on his work in a region beyond the range of vision, and in structures whose size and condition are subject to great variation.

Fig. 4.

Though strong and healthy persons may tolerate the presence of these teeth under exceptionally favorable circumstances, it is generally a safe rule to always remove them from the jaws of delicate persons.

In this connection it is well to point out the possible, nay often probable, danger to health from all fixtures now so commonly worn in the mouth, requiring for their retention the remains of defective teeth, as caps, crowns, bridges, and other metal attachments. Pivot teeth and transplanted or replanted teeth[1] are likewise more or less detrimental, as are also ill-fitting and vulcanite plates.

Tartar cannot be regarded as a disease of the teeth, since its accumulation at any age is due, for the most part, to an excess of alkaline salts in the saliva. Its presence may afford a valuable indication in the treatment of subjects of a gouty diathesis.

In facial palsy, torticollis, chorea, and the like, the influence of diseased teeth and dentition should never be overlooked.

In the treatment of alveolar abscess by removal of the teeth, time should not be lost in waiting for swelling to subside before extraction; nor should pieces of roots or the alveolar process be left to work out themselves.

We all of us, I presume, are reluctant to criticise the well-meant endeavors of others, and in considering the ill-advised and injurious dental work done, sight should not be lost of the commendable advances made in dentistry during the past fifty years. And whatever may be said in respect to the meddlesome treatment of the teeth, especially carious teeth, now so much in vogue, it is largely due to the indifference of the profession toward oral surgery. It is true that medical men have taken up the study of the teeth from time to time, and have by their labors very much advanced dental anatomy and pathology; but it is not to the acquisition of medical knowledge that dentistry is indebted for the development of clever handiwork, but to the special smithcraft of recruits coming from the ranks of metal workers and other skilled mechanic arts.

So long as dentists are wanting in surgical knowledge, unattainable without due course of study, and surgeons taking up this profession are unable to acquire the practical mechanical skill requisite in dentistry, the status of dentists must needs remain undecided, for its recruits come from these extremes.

It would seem that the sooner a greater knowledge of oral surgery than generally prevails is made a requisite for graduation by medical schools, the better it will be for all concerned. But this cannot be accomplished by the es tablishment of dental colleges alone, for oral surgery differs from no other specialty in respect to requiring a regular medical training. Unfortunately, however, for the inauguration of any measures of reform in this direction, the apathy so long existing in the profession as regards the subject has practically excluded this branch of surgery from the domain of medicine, greatly to the disadvantage of those who are called upon to treat neuroses arising from diseases of the teeth. If medical colleges undertake to educate dentists it would be well to bear in mind the necessity for thoroughly equipped laboratories in which metal working may be taught.

12 West Thirty-fifth Street.

SURGICAL TREATMENT FOR LACERATIONS OF THE PERINEUM, WITH SOME IMPORTANT MODIFICATIONS.

By JAMES K. KING, M.D.,
CLIFTON SPRINGS, N. Y.

The operations and modifications that have been proposed and tried for laceration of the perineum are very numerous. It is not necessary to review them here. The careful and laborious studies of the anatomical structures and relations of the female perineum by Ambrose L. Ranney, of New York, and Hart and Barbour, of Edinburgh, and others have given us a much more definite knowledge of the structure, nature, and importance of the perineal body, and have led to a better understanding of the method of operative procedure which will most completely restore the parts to their original condition.

Dr. Thomas early taught (even when other prominent gynæcologists firmly denied its existence) that the perineum was a wedge-shaped body or inverted keystone, and

[1] It has been claimed that teeth may be safely put back in the socket, or even transplanted from a foreign source, and form a healthy union with the jaw. But this so far as known to the writer, at least, has not been satisfactorily demonstrated. Such teeth, it would seem, remain rather as artificial fixtures, becoming tolerated, so to speak, very much as ill-fitting plates do, without causing pain or discomfort even.

that it was all important as a support for the vagina and uterus. In the more recent operations much attention has been given not only to uniting the pelvic fascia and the perineal floor, but the whole perineal body. The old methods, with quill sutures and the like, have been abandoned. Later came the plan more particularly advocated by Dr. Emmet, of employing a number of deep perineal sutures, generally silver.

This operation with its numerous modifications, was the best one devised for a long time, but it has always had two serious objections, and, as Dr. Dudley has shown, has not given complete satisfaction. First, stitches, whether silk or silver, introduced in this way deep in the tissues pass transversely to and include important perineal vessels, cause considerable swelling, and are always painful. Second, deep stitches introduced in this direction when gentle traction is employed resemble in a picture the strings of a harp, but when they are drawn firm enough to keep the parts in apposition, as they always are before being twisted and tied, the soft tissues are dragged downward and the perineal body is shortened from above downward and the posterior vaginal wall is drawn down, and with it the uterus, and this increases the rectocele, although the vaginal orifice is made narrower and hides it from view, results which it is most desirable to avoid.

These defects in the operation have led surgeons, both in this country and abroad, especially in Germany, to develop other methods of operating. Dr. Henry O. Marcey, of Boston, devised his perineal pins which are ingenious and an important addition to the surgery of the perineum, and did much in the way of preserving the anatomical relations of the perineal body. Dr. J. H. Kellogg, of Battle Creek, Michigan, has modified these pins by making them straight, and fastening the vaginal ends with thread and the perineal with silver wire, thus greatly facilitating their removal.

Lawson Tait, Alexander Simpson, and others varied the operation by dissecting up a vaginal flap, and bringing the raw surfaces together with silver sutures, thus repairing the laceration without any loss of tissue. The operation of my friend Professor Simpson is an excellent one for many cases of complete laceration.

This method has had many modifications, Dr. N. Schinder, of Cleveland, dissects up the vaginal flap, divides it in the median line, cuts away the excess of mucous membrane, brings the raw surfaces together in the usual way with deep sutures secured externally, and then stitches the mucous membrane to the lower edge of the vagina, thus forming a cover over the line of union.

But general opinion seems to be growing rapidly in favor of some form of the operation as it has been made in Germany for some years past by Hegar, Kaltenbach, Martin, and others, by which the deeper structures are brought together with buried sutures of some animal substance, as kangaroo, catgut, etc., thus building up a firm perineal body, and over this the mucous membrane and perineal surfaces are united by either catgut or silk sutures.

Dr. L. P. Burt, of Boston, who with Dr. E. W. Cushing has done excellent work in this line, has ably presented the advantages of this method in his article in the *Annals of Gynæcology* for September, 1888.

Dr. A. Palmer Dudley, in the *Journal of Obstetrics*, etc., for December, 1888, presents, in a valuable paper, many new and important facts on the surgery of the perineum, which are of practical value.

In the *New York Medical Journal* for December 29, 1888, Dr. W. A. Wathen, of Louisville, Ky., takes up the other view of the subject, and argues in favor of preserving the tissue and doing the flap or splitting operation after the manner of Tait and others. He presents strongly the importance of uniting the ends of the separated muscles, a matter which is quite generally recognized by operators in the surgical treatment of the perineum. But while these operations make a strong pelvic or perineal floor, they all come short, as Dr. Burt has clearly shown, of completely restoring the whole perineal body and correcting the conditions which are the result of the laceration. The only complete and satisfactory operation is one which accomplishes all these objects.

After a large number of operations and watching the work of other men for years, it seems to me that the only operation which does this is the one in which the buried suture is used after the manner of Martin, or where the vaginal as well as the perineal sutures are employed in a manner similar to that practised by Dr. Dudley, or as in the modified operation which I am about to describe. I much prefer the buried suture in addition to the vaginal and perineal continuous or interrupted sutures, because in this way the most normal perineal body and strongest support can be obtained. The objections to the splitting or flap operation, and to those in which the sutures are introduced from and secured on the perineum are:

1. They only restore the floor or lower part of the perineal body.
2. They do not correct the rectocele.
3. They do not relieve the dragging on the posterior wall of the vagina.
4. They do not form the upper portion of the perineal body anew and give the needed vaginal support to the prolapsed uterus.
5. The flap operation does not remove the old cicatrices.

Little has been said about this last point, but I am certain that in many cases it is a matter of great importance. I operated in one case in which the two large, long scars in the latero-posterior walls of the vagina were extremely tender and caused much reflex pain up the spine. When these were carefully removed, the pains and tenderness disappeared. I have noticed several other less marked cases. This, in my judgment, is a point that should be kept in mind—always remove the cicatrices as far as practicable. If a cicatrix in the cervix uteri will cause so many reflex symptoms why will not a larger one in the vagina, which is much more sensitive, cause many local and reflex disturbances?

I will now describe, as briefly as possible, the method I have adopted, because the results seem to fully warrant it.

Dr. Emmet prescribes, very carefully, the plan for preventing rectocele and prolapsus after delivery, when there occurs extensive laceration of the perineum. This will work well if the patient is under the care of a specialist, but in my own case, and I am inclined to think the same is true of most men who operate much on these cases, the patients who come have had no special care and only come because they want to be relieved of the distressing symptoms. Then we generally find the labia separated from contraction of the muscles and fascia, rectocele, often vesicocele, and the posterior wall of the vagina dragged down, and with it the cervix, into the axis of the vagina and prolapsed.

The object of the operation is to correct as far as possible all these conditions. We make the denuded surface extend from the posterior remains of the hymen on either side back to the median line, and this double triangle to converge to a point as high up as the vaginal wall is distended, which is usually just above the rectocele, taking special care to uncover as far as possible the central tendon and the ends of the perineal muscles on either side (see Fig. 1). The first stitch introduced is the most important one of all, and the one to which I desire to call special attention. It is a long silver suture, and is introduced in this way: A large-sized curved Emmet's needle is armed with fine, stout silk for the purpose of drawing the silver through, or the needle, if care is exercised, can be threaded with the silver wire. The needle is entered at the point of the triangle, at the posterior border of the hymen (care being taken to enter the needle in the denuded surface so it will not cause pain afterward), and is carried in a double curved line downward and backward so that in the median line or posterior part of the vagina it will pass under the denuded surface about three-eighths of an inch from the lower edge of the denuded surface (see

dotted line of suture in Fig. 2). This suture passes under the tissue out of sight all the way, until it emerges at a corresponding point on the opposite side. It is drawn through until the ends are equal, and then is not twisted, but left loose. The reason for this will appear later. The special advantages of this suture are as follows:

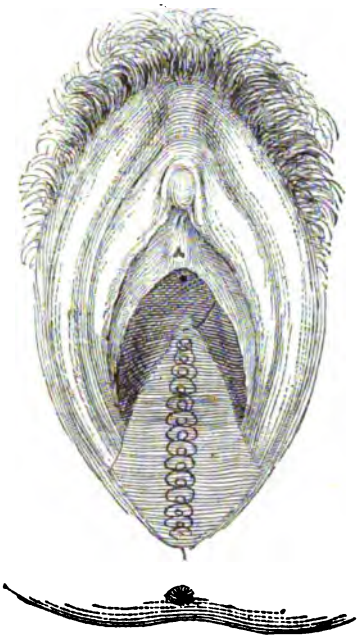

FIG. 1.

1. When drawn moderately tight it holds the perineal body firmly together at its thickest point.

2. It not only furnishes a firm support, but this support is in the natural direction of the constrictor vaginæ and other muscles.

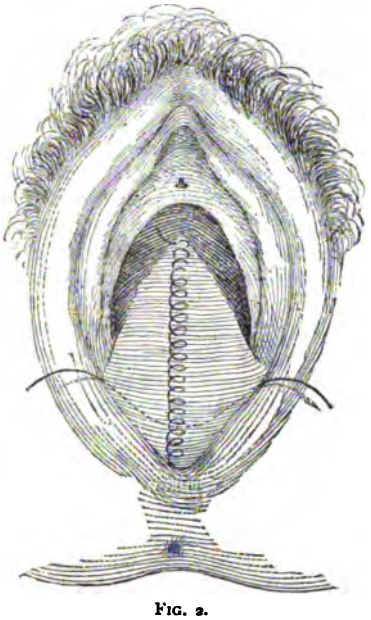

FIG. 2.

3. It brings together the separated transverse perinei muscles, and gathers up the perineal fascia.

4. It does not constrict as many vessels as a deep suture secured on the perineal surface.

5. It does not cause swelling and pain as do the deep perineal sutures.

6. With this strong support much less of the buried suture is required to hold the parts in apposition. This last point is of great importance. If too much catgut is buried in the perineum, one of two results will follow, either the tissues will be too much constricted and the vascular supply diminished sufficiently to prevent healing, or there will be more than will be absorbed and so prevent complete union.

When this special wire suture is used it furnishes the main support, and just enough buried catgut is needed to hold the parts in apposition, and complete union takes place rapidly.

The next step in the operation is as follows: A medium-sized half-curved Emmet's needle, threaded long with No. 3 or 4 catgut, which has been *carefully sterilized*, is introduced into the denuded tissue about three-eighths of an inch from the upper angle, with the forefinger of the other hand in the rectum, and with an over and over stitch, giving the needle a downward and inward curve to the median line, and then outward and upward to correspond, the tissues at the bottom of the wound are brought together. This stitch is carried down to just below or behind the point where the silver suture crosses, and then in the same way it is turned and carried upward, bringing the tissues together over the first line of stitches until the upper angle is reached, then the needle emerges on the mucous surface on one side of the angle, and the next row of stitches, giving the needle the same curve, which draws the perineum

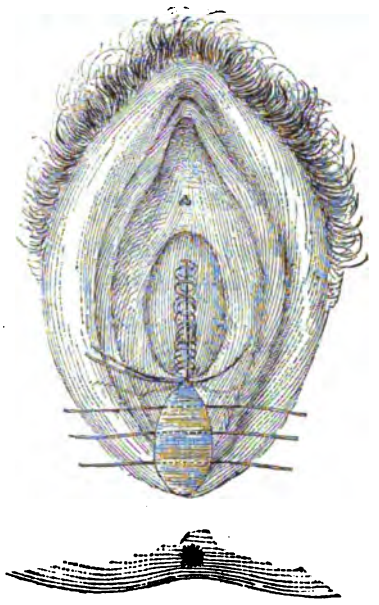

FIG. 3.

upward and forward as it is formed, brings the edges of the mucous membrane together over the two rows of buried stitches. This curved stitch has the same effect in drawing the perineum and vaginal wall upward which Dr. Dudley has described in his excellent paper. He forms an angle with the apex downward and removes the needle, and re-enters it on the other side of the median line with each stitch. I cause the needle to make a curve which seems to give the same result and has the special advantage of saving much time. This last row of stitches is brought down to where the silver suture enters and is secured. It will be observed that as the perineal body is thus built up and the two sides approximate each other the curve occupied by the silver wire has become much shorter. The wire slips out of the tissues as the perineum is raised upward and forward, and this is the reason why the ends are to be left loose at the beginning. The silver suture is now secured in the usual way, but does not need to be drawn as firmly as if there were no buried sutures used. It will now be evident as we approach the third division of the sutures, those in the perineum, that only a small portion of the perineal body, that included within the dotted line as seen in Fig. 3, remains to be brought together. The edges of the central tendon, the muscles, and, as far as possible, the fascia, are united by interrupted silk sutures, using as few and only as deep as is necessary to secure apposition. Finally, a continuous catgut ligature with an over and over stitch, brings the edges of the skin together and forms the raphé. The entire line of sutures is dusted with iodoform, the water drawn, unless there

is some special contra-indication, then the douche is used after each evacuation of the bladder. The bowels are confined for from four to eight days, according to circumstances. It is a much disputed point as to whether or not it is better to move the bowels every day, or to confine them for a number of days. It seems to me the question depends on the variety and extent of the operation. In the flap or splitting operation, or any one in which only the lower portion of the perineal body has been restored, there is little danger of disturbing the line of union when a loose movement is secured every day. If, however, the whole perineal body has been restored there is much danger of disturbing the healthy process in the upper or vaginal portion, and it is better to have the bowels quiet for four days and longer if no serious inconvenience arises. I remove the silver sutures the seventh day, move the bowels carefully the eighth day, and allow the silk stitches to remain until the ninth day. In cases of complete laceration the rectum and sphincter ani are sutured, and then the rest of the operation is the same as described. In cases where the vagina is much relaxed, posterior colporrhaphy can easily be performed as a continuation of this operation.

I am sure that a fair trial of this method of operating will give the most gratifying results.

IRRITATION AND THE TREATMENT OF RINGWORM OF THE SCALP.

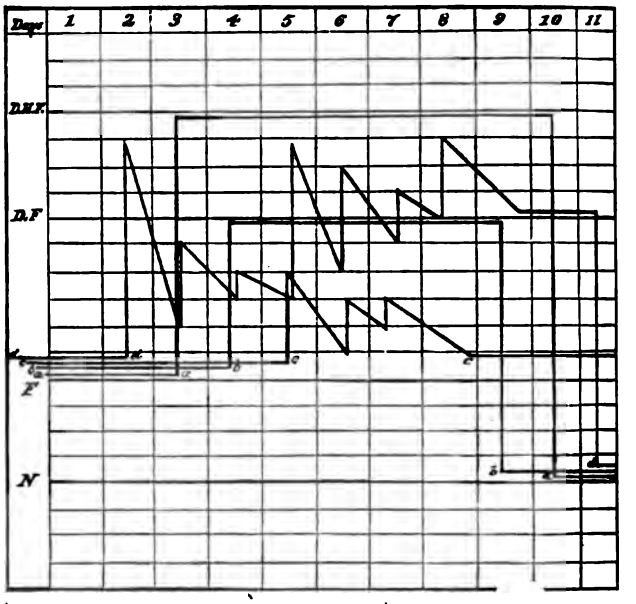
By FRED. J. LEVISEUR, M.D.,

PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL AND DISPENSARY, N. Y.

In a "Rapport à l'Académie de Paris," M. E. Besnier, one of the most prominent French dermatologists, recently said:

"In the present state of science we have no therapeutical agency at our disposal which has the quality of modifying the living cell in such a manner as to render impossible the germination of the microphyte or microbe without damaging at the same time the vitality of the cell, causing local destruction, or even death of the whole organism. Our progressive tendencies should be directed to the study of this question far more than to the search for new parasiticides of imaginary value. The modification which living organic tissue may undergo is plainly shown by the various kinds of vaccination, rendering the cells unfit for the growths of certain microbes. It is shown in regard to the microphytes by the changes in the development of the hair, which, in the adult, becomes absolutely refractory to the germination of trichophyton, while it offers a favorable soil to other parasites."[1]

It is a fact that our therapeutical armamentarium has become very large, and that we do not need any more new antiparasitic remedies for the cure of ringworm of the scalp. As to the new methods devised in order to make remedies sink deeply into the skin and hair follicles, where they are supposed to meet and kill the parasite, I think that they are based on some primitive pathological knowledge. As Professor Campana[2] has recently shown trichophyton tonsurans may invade the deeper layers of the skin and properly vegetate in them. The exact mode of action and the proper method of applying the remedies undoubtedly calls for some further investigation. Do the antiparasitic remedies act as such, or by virtue of their quality as irritants? Does the principle of managing ringworm of the scalp consist in producing in the hair follicles an inflammation sufficiently acute to gradually lead to the destruction of the fungus,[3] or can remedies which cause no perceptible irritation surely, though in some cases slowly, exterminate the disease?[4] These are questions raised long ago,[5] and even nowadays not yet definitely settled. So much, however, is evident to a certainty, that, when treating cases of ringworm of the scalp, we have to take special care in properly controlling the irritation produced upon the skin by the remedy which we are using. In doing so we will carry out not only an important precautionary measure, but also make good use of whatever beneficial action irritation, properly controlled, may have in bringing about a cure. What I mean is plainly shown in the accompanying diagram. We take the normal condition of the skin *N* for a basis.



The next higher degree of irritation, *F*, is that caused by the presence and growth of the fungus. *D F* stands to mark the amount of irritation which is necessary for the destruction of the fungus, and *D H F* for that necessary to cause the inflammation and destruction of the hair follicles. *N* and *F* are conditions which present themselves to the eye of the observer, and can therefore be accurately estimated by the latter. They vary, of course, in every individual case, but bear a certain proportion to each other, which we are able to ascertain, and which thus enables us to draw a conclusion on the situation of *D F* and *D H F* in our curve. If the normal condition of the skin of a patient is a delicate one, the growth of the fungus needs very little intensity to cause a lively irritation of the skin; if, on the other hand, it is more indolent the irritation will hardly be noticeable.

These and similar considerations enable us to make a pretty good guess as to the amount of irritation which would cause a destructive inflammation of the skin (*D H F*), an accident which we always have to avoid. We are accustomed to draw a conclusion in just the same way from the amount of redness and irritation present in a case of eczema, and to settle accordingly on a soothing or more or less stimulating plan of treatment.

In gonorrhœa—to take a disease of an entirely different character for an example—the subjective symptom of pain, together with the amount and aspect of the discharge are sufficient indications to influence our selecting an injection of varying strength, quality, and mode of application, no matter if we start with the intention of killing the gonococcus or applying an astringent to the mucous membrane of the urethra. The amount of irritation necessary to destroy the fungus (*D F*) is not known to us, but it must be located between *F* and *D H F*. We have to endeavor to strike this line, wherever it may be situated, between *F* and *D H F*. We reach it in exceptional cases in our first attempts at treatment, effecting a surprisingly quick cure. In the majority of cases, however, we are accustomed to feel our way, and, by frequently changing our remedies in quality and strength, or by suspending treatment entirely for a while, to see if we have been successful in reaching it.

[5] Sir Erasmus Wilson: Cutaneous Medicine, etc., p. 383. 1865.

Let us now first trace in our curve the course which nature sometimes takes in order to cure ringworm of the scalp, and let this serve as a lesson. It is the condition known as "kerion," rarer in this country than abroad,[1] occurring idiopathically as well as by the use of popular remedies, or by overtreatment of the disease. The irritation arises often suddenly, sometimes gradually, to a degree sufficient to cause destructive inflammation of the hair follicles (*D H F*). This maximum of irritation lasts for days, and even weeks, and then disappears, allowing the skin to return to its normal condition (see line *a*, in the curve). We have carefully to avoid the production of kerion, because it results in permanent baldness of the affected spot. It teaches us, however, that in order to cure the disease a state of irritation is necessary, which has to continue uniformly for a certain period. If we knew exactly the location of *D F*, that is, the amount of irritation necessary for the destruction of the parasitic vegetation, and if we could keep the skin in this irritated condition for a certain length of time, we would have reached the ideal. This is demonstrated in our curve by line *b*.

Being in the dark about the location of *D F* we generally commence, and frequently continue, with an insufficient manner of treatment, as shown by line *c*. Afraid of the danger of causing deep inflammation of the skin, kerion, we select a remedy the application of which produces an irritation not intense enough to be destructive to the parasite (*D F*).

And if even we reach *D F* we will have produced only a passing irritation which quickly decreases, and the continual application of the remedy of the same strength will finally result in adding only some irritation to that already existing on account of the presence and growth of the fungus. This is explained by the general law that irritants of uniform strength continually applied to the skin lose their irritating qualities.

Cases of so-called irritated ringworm are often the consequences of this defective plan of treatment.

What would now be the best way of profiting the most by the irritating qualities of whatever remedy we apply?

First, to produce an intense irritation of the skin not far from destruction (*D H F*); we have to do or superintend this personally, because our success depends on our carefully considering the normal condition of the skin and the amount of irritation produced by the presence of the fungus. An additional point is this, that the skin of those spots which have been carefully epilated by an experienced hand is able to stand a good deal more of irritation than the rest of the scalp.

After the irritation caused by this application has mostly subsided, a milder remedy is applied to the patient's head, by a nurse or an attendant, at regular intervals. The first or stronger application is then repeated by the physician himself, and this in turn is followed by the regular use of the milder application.

As is shown in the curve (line *d*), the amount of irritation, steadily increasing, reaches *D F* and remains near this line for a certain period.

Being asked through the kindness of Dr. S. Baruch to treat an epidemic of ringworm, which had broken out on the scalp of some of the inmates of the New York Juvenile Asylum, I had ample occasion to ascertain the fact that it is of great practical value to have constantly in mind the points I have mentioned above.

From the notes which I have collected while treating the cases I will select those which have some reference to irritation.

Ninety-eight children were affected by the disease, which presented itself mostly in its chronic form. There were four or five cases of so-called irritated ringworm and two of true kerion. In age the children ranged from six to fifteen years. Microscopical examination showed the presence of the fungus in the scales and hairs taken from the heads of most of the patients. Treatment was begun in the following manner: The hair was cut short with a pair of scissors close to the scalp and some of the affected spots carefully epilated. It is absolutely necessary, I think, that the physician himself, or an experienced nurse, practise epilation. To leave this important part of the treatment to a hand untrained for the purpose not only recalls to mind the cruel times of the "calotte" by its being very painful, but is also the source of much undue irritation, which it is very important to avoid, as I have said above.

A lotion consisting of simple tincture of benzoin and bichloride of mercury, in the proportion of one to three hundred, was then applied all over the scalp.

A soft nail-brush was used for this purpose, and the lotion brushed into the scalp quite vigorously. The length of time and the mechanical force consumed in this process was modified according to the condition of the normal and diseased parts of the scalp.

The nurses were instructed to wait until the irritation set up by this measure had disappeared, and then apply daily a salve of ten per cent. of salicylic acid with vaseline as a constituens. As a rule, the irritation had passed away the next morning and the salve could be used. If, however, the irritation persisted, or even pustulation occurred, the scalp was left entirely alone till these symptoms had disappeared. I selected the vaseline as a basis for the salve, in preference to greasy matters, because the latter are liable to become rancid and consequently irritating beyond control.

Epilation followed by the application of the lotion was repeated in the same manner in intervals of a week. I gradually increased the strength of the lotion, as well as that of the salve, till the former reached two to three hundred and the latter twenty per cent. It was astonishing how quickly the disease yielded to this treatment and the symptoms of irritation or inflammation disappeared. Whenever a case seemed to be cured treatment was suspended for a fortnight and the patient discharged if no sign of the disease had reappeared. From time to time the discharged children were examined again. I began treatment in the commencement of October, and at the end of February nearly half of the number of patients were cured.

OVARIAN PROLAPSE.[1]

By E. S. McKEE, M.D.,

CINCINNATI, O.

Definition.—A dislocation of one or both ovaries downward, and usually posteriorly. It is true that it is often rather a symptom than a disease, but it displays certain symptoms peculiar to itself.

Frequency.—It is much more common in multipara than in nullipara. It was found by Mundé in 77 out of 145, palpable out of 1,600 unselected cases. From my own experience I am convinced that ovarian prolapse is far more frequent than generally supposed. Many patients complain of a dull, sickening pain, usually referred to the left inguinal region, and in many instances, if investigation be made, it will be found due to ovarian prolapse.

Varieties.—We may have:

1. Retro-lateral: into the lateral pouch of Douglas.
2. Retro-uterine, in the true pouch of Douglas.
3. Ante-uterine: in the anterior or vesico-uterine pouch; very rare.
4. Into the infundibulum of the inverted uterus, which is a position of the greatest rarity, one case only occurring in the practice of Professor Simpson, of Edinburgh.

Etiology.—Factors which lead to an increase in weight, induce traction from below or pressure from above, or cause feebleness or lengthening of supports,

[1] Read before the Kentucky State Medical Society, May 9, 1889.

come under this heading. Among the predisposing and exciting causes may be mentioned the conditions present in the puerperium. These favor displacement for two reasons: The normal ascent of the uterus during pregnancy may stretch the ovarian ligament, and the ovary may not return to its normal size after parturition. Parturition is especially prone to this trouble, if often repeated. Simple congestion resulting in enlargement of the ovary may cause it to descend. Congestion may be an occasion, and again a result, of the displacement, which usually aggravates it exceedingly. Other causes are displacements of the uterus, especially the posterior ones, and prolapsus. The violent straining at stool which is sometimes occasioned by retroflexion may be the determining event of the displacement.

Inflammatory conditions due to cellulitis and to peritonitis, tumors, ascites; vesical, fecal, or gaseous distention pushing from above; the feebleness and lengthening of supports resulting from subinvolution, frequent parturition, and general debility. In rare instances acute displacements may be caused by sudden jolts or jars. We may have this displacement owing to simple increase in weight of the glands, prolonged hyperæmia from sexual excess, or chronic oöphoritis. A displaced ovary is at once the cause and the result of disease. A perfectly healthy ovary chained down by a retroverted uterus has its circulation at once more or less obstructed, and it then becomes the seat of chronic changes. This will more probably occur if buried in adhesions. Accompanying this dislocation some uterine tension is usually found which we must consider as cause or effect. This cannot well be otherwise, for the vascular relationship between the two is so close that turgidity in the one means erectility in the other. In the displacement of the ovary downward into Douglas' pouch, the most common form, the causes are more frequently gynecological than obstetrical. The pressure of the sigmoid flexure on the left side accounts for the more often occurrence on that side. Fulness of the intestine is a common cause. Robert Barnes has observed that the Douglas pouch is much deeper on the left side than the right. The left ovary is more usually prolapsed, not only because it is more subject to disease, but by reason of its greater enlargement during pregnancy. There are several influences which tend to produce this condition. Chief among these is the valveless state of the left spermatic vein, which makes this vessel easily affected by an obstruction in the general circulation. The conformation of Douglas' pouch allows the left ovary to sink lower than the right, and makes it more accessible to the examining finger. Simultaneous primary dislocation of both ovaries is not common. Very thin women are more prone to this disease than fat ones. Congenital malformation may occur, and subinvolution of the broad ligaments will in some instances allow the prolapse of the ovaries when not enlarged.

Pathology.—The enlarged ovary usually occupies an abnormal position, often very sensitive to the touch, and sometimes fixed by peritonitic adhesions, also often accompanied by displacements of the uterus. The usual mode of procedure is for the ovary, generally the left, to sink downward and backward, and at the same time to describe an arc toward the median line. The Fallopian tube and ovarian ligament form chords. This brings the ovary behind the uterus, unless the latter remains in its normal position. The ovary in its descent reaches that portion of pelvic fossa just above the level of the sacro-uterine ligament known as the retro-ovarian shelf, where it may remain. As this space on the left side is encroached upon by the rectum, the corresponding ovary is inclined to slip down still further into the cul-de-sac of Douglas. When both ovaries are prolapsed the left lies at a lower level, and is more accessible to the examining finger. A perfectly healthy ovary lying in the posterior cul-de-sac is placed under the most favorable conditions for congestion, mechanical injury during sexual intercourse leading to subacute inflammation which is attended by peri-oöphoritis and fixation of the gland in its abnormal position. Where due to subinvolution the ovary follows the uterus.

Symptomatology.—Spasms of radiating, throbbing, neuralgic pains of a sickening and unnerving character, often occurring suddenly, are felt in the pelvis and surrounding parts. Marked pain on walking and coition, with torturing pain on defecation caused by the grating of hardened fæces on the tender glands, especially in prolapse of the left ovary, are experienced. Sickness and nausea on pressure by the examining finger, similar to that felt on squeezing the testicles, dragging sensations in the groin and down the thighs, nervous symptoms with general irritability, severe hysterical symptoms, and melancholia, are among the indications. These are local and general, as a rule very well marked and severe. These symptoms much resemble those due to severe retroflexion of the uterus. Having associated the two conditions, ovarian prolapse and retroflexion, the symptoms may be doubly intense. Derangements of menstruation, usually menorrhagia, are sometimes present. General reflex neuralgiæ are often found, a frequent seat being in the breast, and in fact usually confined to the side on which the ovary is affected.

Physical Signs.—Bimanually we feel, in the true or lateral pouch of Douglas, a small body or bodies exquisitely tender and lying distinct from the uterus; on rectal examination the ovary is felt with unusual distinctness. The finger should be carried as far upward on either side of the cervix uteri as the vaginal wall will permit, and then brought downward toward the sacrum, so that if the ovary is caught it will be between the examining finger and the sacrum. By this means it can be outlined by palpation, and its sensitiveness determined. The degree of mobility or fixation can also be thus determined. In many instances the ovary lies so exactly central that it is impossible to tell whether it is the right or the left, until the other one is found in its normal position. If the prolapse is incomplete the ovary is generally discovered at one side of the uterus, usually a little above the junction of the body and the neck.

Diagnosis.—As a general thing this is not difficult. It may be distinguished from enterocele by not being smooth and globular, nor giving rise to gurgling on compression, or resonance on percussion. It may be differentiated from epiplocele by the absence of the peculiar, soft, doughy feeling and the irregular, ill-defined outline of the latter. A displaced ovary may be diagnosed from enlarged inguinal glands by the smaller size and simultaneous appearance of several glands in the same situation in the former case. A prolapsed ovary in Douglas' space may be distinguished from a posterior uterine displacement or tumor by recto-vaginal examination and the use of the sound. As a rule, in displacements of the ovaries there is pelvic tenesmus and pain on walking or standing, relief being obtained by the recumbent position. If the prolapsus is complete the ovary feels not unlike the fundus uteri and gives the impression of retroflexion. The tenesmus and pain in walking is a discriminating point against inflammation of the ovaries. Differentiation from retroflexion can be made by the peculiar sensitiveness of the ovary to pressure, and by the fact that the finger can usually be passed between the uterus and the ovary. Should doubt still remain, the passage of the sound will settle the question. In case both retroflexion of the uterus and ovarian prolapse should exist, we can solve the problem by lifting the uterus, by means of the sound, off the ovary, which remains *in situ*. The prolapsed ovary may be mistaken for a pedunculated fibroid tumor. It may be distinguished from scybala by the absence of the mobility, softness, and comparative sensitiveness.

It is good practice to explore the posterior cul-de-sac while the woman is in the left lateral position, as the perineum can be pushed upward at least half an inch, and the finger reaches that additional distance along the posterior

vaginal wall. Rectal examination will enable one to reach at least an inch higher up into the pelvis than by an examination per vaginam. In obscure cases this mode is of great service. If a thorough examination is not easily attained, an anæsthetic will aid in clearing up the difficulty. Sensations of size conveyed by touch in the diagnosis of this trouble are deceptive. As a rule, prolapsed ovaries are larger than they appear, since only a small portion of their surface is accessible to the finger tip. In the diagnosis of mobility of the ovary, we must not mistake elevation of the pelvic contents en masse for actual lifting of the ovary.

PROGNOSIS.—The question as to whether the displacement can be permanently overcome depends upon its duration; upon the condition of the ovary, whether normal or diseased, and whether there are other complications, such as adhesions, retroversion, or retroflexion of the uterus. In cases of recent date which are free from complications, permanent relief may be obtained. In many involved cases all local treatment fails. Though the life of the patient may not be directly implicated, yet the ovary after a time is liable to become congested and sensitive, and ultimately result in inflammation and changes of the organ.

TREATMENT.—Is essentially local, and unfortunately the results are not especially brilliant. Oöphoritis being present, sexual intercourse, if permitted at all, should be carefully regulated. The bromides and ergotin exert a happy effect. If the prolapsed ovary is movable it may in some cases be lifted out of harm's way by a pessary. Many cases can be relieved or cured by keeping the intestines empty with mercury. Should the organ be very sensitive or irritable, this condition should be removed by the use of tampons saturated with glycerine. Great benefit is to be derived, in displacements with parametran infiltrations and hyperæmic conditions of the uterus and adnexa, from a firmly packed column of cotton. The advantage of the cotton tamponade is that it accomplishes the same result as a pessary without exercising the same pressure. Bozeman's method of packing or columning the vagina, with the patient in the knee-chest position, offers superior advantages, since it includes the two elements—pneumatic reposition and firm, continual pressure. Suppositories of iodoform, belladonna, tannin, or iodide of lead, applied directly to the sensitive spot and held there by tampons, afford relief. After congestion and pain are alleviated, in some cases a pessary will answer very well, but in my experience these instruments have been of little benefit. The one used has the cross-bar made broad and thick. The bulb pessary aims at the greatest degree of distention of the postero-formix, and in this way to elevate the displaced organs. Many modifications of lever pessaries have been devised—Thomas' bulb pessary, Gehring's retroversion pessary with central depression, or one of Thomas's bulb pessaries similarly or unilaterally bevelled out. The retention of a prolapsed ovary by means of a pessary is by no means so easy as the fundus uteri. The extreme mobility of the ovary renders it very liable to slip down behind the pessary, when the pain thus occasioned will soon demand the change or removal of the instrument. An air-cushion or Gariel pessary may be introduced with advantage. These lessen the pressure, but soon lose their shape. An indentation in a hard-rubber pessary at the point where it presses on the ovary, sometimes works like a charm. Cases in which pessaries are of benefit are usually those in which there is accompanying uterine displacement. In simple ovarian prolapse they usually do more harm than good.

If the ovary has become fixed in an abnormal position as a result of peritonitis, the prospects of success from palliative treatment are not encouraging. The persistent use of the tampon, hot water injections, local applications to the formix, and cotton soaked in some emollient, will prove of benefit. We should explain the condition of the patient to her, tell her it is a case of months, not weeks, and we should patiently and persistently treat them for six months before the question of laparotomy is seriously considered. Though this routine treatment may appear very unsatisfactory, yet it is not to be despised.

For severe pain in the ovaries, rectal suppositories may be used containing cannabis indica, belladonna, iodoform, or opium, and rectal injections of hot water as hot as can be borne. Blisters are sometimes of value applied over the ovarian region. Absolute interdiction of sexual intercourse is necessary in many cases. Rest in the recumbent position for an hour, two or three times a day, is of great benefit. An abdominal brace will sometimes help by forming a sort of shelf on which the viscera may rest, and thus relieve the ovaries of a portion of their load. It also aids by narrowing the pelvic inlet and by swinging the pelvis backward.

Although pregnancy is a cause of ovarian prolapse, in my experience it has in several instances proven a cure for the disease. If pregnancy is oft repeated it is frequently an etiological factor, but if occurring at periods separated by considerable intervals, it may become a remedy where ovarian prolapse exists, as when the fundus uteri lifts itself out of the pelvis it lifts the ovaries with it. When the pregnancy is completed the circumstances may be more favorable, and the ovaries remain in their proper place.

The method of Dr. Henry F. Campbell, of Augusta, Ga., described in his excellent papers on posture in the treatment of pelvic troubles, relates the success attending the pneumatic reposition of the displaced organs. This is done by placing the patient in the knee-chest position and opening the vagina to allow the air to distend it; it may be used with much benefit in those cases where the ovaries are freely movable. If this be repeated at least twice daily, the strain on the relaxed ligament and vessels is so relieved that the latter tend to recover their tone, and the patient experiences a decided amelioration of her symptoms. If she wearies of this position, after filling the vagina with air she can lie over on her side with a pillow under her hips and her shoulders low, thus keeping up the position without tiring herself. Goodell recommends that in this position the patient separate the labiæ with her fingers and allow the air to enter. Campbell uses a glass tube, which is inserted by the woman. Both of these means are unnecessary, as the ovaries will resume their proper place from the knee-chest position alone. Dr. Campbell advises that the woman kneel on the bed with her body bent forward until her chest is brought down to the surface, head turned to one side, and cheek resting on the palm of the corresponding hand. Her knees should be about ten inches apart, and her thighs perpendicular to the bed. If she now refrains from straining, and breathes naturally, the force of gravity will do the work. Such replacements are of great value. They replace the organs, relieve congestion, give the limp ligaments a chance to shrink, and keep the truant ovaries at home.

Extirpation of the ovaries, a *dernier ressort* for this trouble, sometimes becomes a necessity. The vaginal operation, which at first was considered especially applicable to these cases, has not justified the hopes of its originators.

Oöphorhaphy in place of oöphorectomy, as a means of treatment, has been highly recommended by Imlach, of Liverpool. In the virgin the ovaries slope inward, forward, and downward, and are suspended by the so-called infundibulo-pelvic ligaments, or peritoneal folds of the broad ligament, stretching from the pelvic brim to the infundibula of the Fallopian tubes, and contain the ovarian vessels. This operation seems most applicable to cases of recent or acute prolapse. After childbirth these folds are relaxed and the ovaries are suspended by the utero-ovarian ligaments. The relaxation of the infundibulo-pelvic ligaments being exaggerated, the ovaries hang vertically downward, become congested and painfully prolapsed, whether the uterus is retroverted or anteverted. By this suture, which might be termed "taking a reef,"

the hilus of the ovaries are sewed to the relaxed infundibulo-pelvic ligaments near the brim, the virginal position of the ovaries was restored, the Fallopian tubes folded over them as before, and this was oöphorhaphy. When retroflexion of the uterus was present this condition was also cured by the operation. Anteversion and flexion were not rectified, though the symptoms were satisfactorily cured when dependent on prolapsed ovaries. Tait's operation for this condition consists in puckering up pieces of the broad ligament in a ligature, and so shortening the ligaments in all diameters. He raised the inflamed ovary to a higher level, but failed to give the desired relief. It is questionable whether this organ will remain permanently elevated, and it is not reasonable to believe that it will be cured if actually diseased. Few operators of the present day would stop before totally extirpating the organ, which will, of course, sooner or later, be the resource according to the experience or tendencies of the operator. The Weir Mitchell rest-cure is an indirect method of treatment which is sometimes of much benefit.

Hysterorhaphy affords more or less relief to patients whose ovaries are prolapsed, since the glands rise up in the pelvis as the uterus is elevated, and if deemed advisable the ovaries can be removed at the time of the operation. Pelvic massage is of benefit if the ovary is not too sensitive. It consists in making steady upward pressure on the gland with the index, or tip of the index and middle fingers, for one or two minutes, varied with occasional rubbing or kneading movements, while the other hand makes counter-pressure on the abdomen and down the uterus forward. This should be very carefully done, and discontinued if causing any undue pain or increase of tenderness.

Electricity in the form of galvanism, applied two or three times a week in séances of ten or fifteen minutes, strength 15–20 milliampères, is a valuable means of relieving the pain. The negative pole, with a large flat sponge or copper plate, is placed over the abdomen, and the ball electrode positive pole in the vagina.

Schultze's method of replacing the prolapsed ovary may be undertaken if all evidences of acute inflammation have ceased, and the presence of dangerous tubal disease has been excluded. This consists of etherizing the patient, placing her in the lithotomy position, and introducing the forefinger of one hand into the rectum, while the other hand grasps the fundus uteri above the fundus, and draws it forward. The rectal finger in contact with the imprisoned ovary seeks for an interspace between the gland and the surrounding adhesions, into which it is gradually bored until the latter become detached. The pressure is always made against the adhesions, not upon the ovary itself. The patient must be carefully guarded against subsequent peritonitis. Tampons or pessaries should be introduced to elevate and retain the ovary after it has been freed. This method is also applicable to cases in which the uterus is retroflexed and adherent. The ultimate results of this treatment are not well enough known as yet to allow its hearty recommendation.

Clinical Department.

REPORT OF A CASE OF PUERPERAL PERITONITIS WITH PECULIAR HEART MANIFESTATIONS.

By E. BIGHAM, M.D.,

ELSIE, CLINTON COUNTY, MICH.

MRS. T——, aged twenty-seven, was taken in her second confinement about two o'clock Thursday afternoon, December 28, 1888. I was called in about twelve o'clock of the same night. I made an examination and found the os dilated about two inches, with the parts rigid and with an inclined presentation of vertex to the right, with the left parietal protuberance presenting. I attempted version of the vertex by bimanual pressure between the pains, with the patient in the knee-chest position, and after the third attempt a complete vertex presentation was secured. From this time on her labor was normal but hard, and about eleven o'clock on the following morning an eleven-pound child was born. I worked about half an hour, using Credé's method for expulsion of the placenta, but as it seemed to be, and was, adherent, I anointed my hand and arm with a three per cent. carbolized ointment, and introducing my hand carefully into the uterus, succeeded in detaching and removing it. The external genitals were carefully washed with carbolic solution and the patient was left to rest.

I saw her again in the evening. The temperature and pulse were normal. On Saturday morning and evening I found pulse and temperature still normal, but as the patient expressed it, "I feel, oh! so tired." About eleven o'clock of the same night I was summoned in great haste, as the patient had had a chill. I found her suffering intense pain in the right hypogastrium. I diagnosed local peritonitis, fast becoming general. The temperature was 105°, pulse 120. I gave hypodermic of morphine ¼ grain, atropia $\frac{1}{150}$, and repeated the dose in an hour. Tympanites developing rapidly, hot applications were ordered, with turpentine stupes to the abdomen. I gave as an antipyretic 4-grain capsules of antifebrin and 5-grain capsules of quinia, alternately, every two hours. As depression was marked, I ordered two teaspoonfuls of alcohol as a sling, with four ounces of milk, every two hours. The patient continuing to grow worse, Dr. Campbell, of Ovid, was called in counsel, Wednesday, January 6th. He examined the patient carefully and detected a mitral murmur, and ordered digitalis and strychnine.

The patient continued about the same, the temperature ranging from 102° to 105°, and the pulse from 90 to 130, until on the morning of the ninth day of her sickness, when she called her husband to her bedside, and said that her heart had "flopped over," and that he must go for the doctor.

Upon my arrival I found the pulse 150 per minute, and it kept gradually increasing, hour by hour, until, at eleven o'clock at night, it was about 200 per minute. From this time until about two o'clock on Monday morning I could detect no pulse at the wrist at all. At this time the pulse began to be perceptible, and it gradually slowed down, and at four o'clock in the morning it stood 165—at six o'clock, 150—at ten o'clock, 140—and at twelve o'clock, as I sat down by the bedside, it was running at 135 per minute. While I was talking with her husband the patient said: "My heart has just snapped now, and don't run that way." I immediately put my finger on the pulse, and it was running 78 per minute, and strong. I do not think her pulse after that (except at one time, when it ran quite rapidly for an hour) was over 94 or 96 per minute. After this attack of heart trouble her abdomen, which had been very tympanitic, was greatly reduced by the continual expulsion of flatus.

From this time on her symptoms gradually amended until, about the twentieth day, a pelvic cellulitis on the

left side lighted up, ran its course, developing into a pelvic abscess which discharged per vaginam. I used large vaginal injections of between one and two gallons of water, as warm as the patient could tolerate it, every six hours, during her sickness, gradually lessening the number until only two a day were used, and these were continued until all pelvic tenderness had passed away.

I also used a succession of flying blisters across the hypogastrium, and ordered a ferruginous tonic. I am happy to say that my patient is now alive, and, as she expressed it a few days since, "I feel as well, if not better, than I ever felt before."

I have given the symptoms somewhat in detail in the hope that they might throw a little more light on the case. I offer no explanation of the peculiarities of it. I would say, however, that the mitral murmur spoken of, I now fail to detect since the patient has regained her health.

SYPHILITIC STENOSIS OF THE LARYNX WITH TRACHEOTOMY.

By JOHN H. BILLINGS, M.D.,

ASSISTANT SURGEON METROPOLITAN THROAT HOSPITAL.

We recognize among the disorders attending syphilitic manifestations in the larynx the peculiar disposition to chronic inflammation, as represented by alteration of the voice to what might be called a characteristic hoarse quality.

Moreover, grave respiratory symptoms are by no means unlikely to be intercurrent in the course of the so-called tertiary period of invasion; first, of a neurotic character, either peripheral or, more commonly, of a central origin, or as a result of local obstruction in the larynx itself from gummatous formation, by which the glottis is mechanically narrowed to a greater or lesser extent.

This latter condition must naturally occasion great anxiety to the attending physician, inasmuch as with him rests the responsibility of determining the term of impending suffocation before resorting to operative interference, which, while ordinarily of no intrinsic danger, is nevertheless regarded as an alternative to be justly avoided so long as constitutional measures give any promise of inducing resolution of the new formation.

It will be found, however, in a certain number of cases, that owing to a personal idiosyncrasy, antisyphilitic treatment fails to check the disposition to extension of the disease, or else, when carried to a point of forced tolerance, it is liable to induce such laryngeal irritation as to add still further to the danger arising from dyspnœa.

Under these circumstances there can be but little difference of opinion as to the advisability of an early tracheotomy, with the view of avoiding the possible risk attending respiration from too prolonged a delay; but more particularly to permit a treatment at once energetic and leading to a speedier dissipation of the infiltrating gummatous tubercle before the production of an organized and permanent tissue.

The following case serves to illustrate in a measure the conditions referred to, and, in its results, a more speedy recovery to a normal state than would have been looked for under other forms of active treatment.

Mrs. A. B——, aged thirty-five, married, was admitted to the Metropolitan Throat Hospital, October 3, 1888, suffering from intense dyspnœa with aphonia, and general symptoms of laryngeal obstruction. She gave a distinct history of syphilis extending over a period of four years, although decidedly difficult breathing had been observed only within the past three months, exhibiting a disposition to steadily increasing obstruction. Dr. Clark, of Newark, N. J., by whose advice she was brought to the hospital, stated that in the course of his treatment any determinate resort to the iodide of potassium at once caused such sudden and alarming symptoms from irritation and dyspnœa as to forbid its continued use.

On examination a large gummatous swelling was found involving the aryteno-epiglottic fold, the false bands, and extending so widely as to overhang completely more than half the glottic space.

Tracheotomy was performed the following day by Dr. Clinton Wagner. But little difficulty was found from hemorrhage in the course of the operation, although, owing to an unusually enlarged thyroid, the opening into the trachea had to be made at a lower point than ordinary.

The patient made a quick rally from the operation, and all danger from suffocation now being removed, the constitutional treatment was rigorously pushed, the iodide of potassium being given in full doses, increasing until four hundred grains per diem were taken.

The improvement was so satisfactory that the tube was permanently removed at the end of the third week, and before the patient was finally discharged—two months from the time of the operation—the tissues had so far returned to their normal condition that nothing more than a slight irregularity in the place of the former infiltration remained. The voice was good and strong, and the respiration perfect.

The iodide is still continued, in such moderate quantity as can be well borne, to preserve a constitutional effect, although there has been no disposition to a return of any of the former symptoms of the disease.

249 Madison Avenue.

OLIVE-OIL AND GALL-STONES.

Dr. John Trumbull, of Valparaiso, Chili, writes: "What, may I ask, are the facts with regard to the efficacy of large doses of sweet-oil in cases of gall-stones? Having been called to a case of repeated attacks of hepatic colic, where the diagnosis had been one of 'sand' from the gall-bladder, and the treatment simply subcutaneous injections of morphia for the relief of pain, with instructions as to diet, I referred the trouble to gall-stones, and advised the trial of large doses of olive-oil. At the second dose eight good-sized stones, as I fancied, were passed. Certain it is, that relief from the distressing attacks of colic has been attained; but I was chagrined to find that the stones(?) gradually vanished by absorption into the card-board box in which they were kept. The remains of what looked at first like gall-stones I boiled in alcohol, to find if cholesterin crystals would be deposited on cooling. The only product was a greasy film which deposited on evaporation of the alcohol. As a check on the result of the treatment, I myself took about eight ounces of sweet-oil, and in the evacuations found a large number of much smaller greenish-yellow masses, which likewise contained no cholesterin and went through a similar process of dissolution. Are not the truly remarkable results occasionally published due, therefore, in reality to the formation of fatty masses, closely resembling gall-stones, which are produced in the intestinal tract from the oil taken?"

Some Centenarians.—The Lafarge Tontine, which was formed in 1791, affords a curious illustration of the truth of the saying that annuitants live long. The last subscriber has only just died. Originally there were 116,000 subscribers, and the amount thus obtained was 59,000,000 francs. The dividends of those who died were to increase those of the survivors up to 3,000 francs per share, a limit extended in 1809 to 6,000 francs. The surplus was to go to the state, one object of the tontine being to reduce the national debt. In 1886 there were 17 survivors, holding 162 shares. Twenty of the shareholders were centenarians, and one reached the age of 106. Among the deaths registered in England and Wales in 1887 were 60 of reputed centenarians—13 men and 47 women. In the three preceding years the numbers had been 58, 63, and 71, respectively. Thirty-two are said to have reached 100 years, ten 101, and two 106 years, and two women are said to have been 107 and 109, respectively.—*British Medical Journal.*

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, June 1, 1889.

MARRIAGE AND INSANITY.

As public intelligence increases and the important part played by heredity in determining human character and happiness becomes more widely recognized, medical opinion upon the subject of marriage will more often be consulted. Already the questions of marriage and phthisis and of marriage and syphilis have been thoroughly discussed, and a considerable uniformity of opinion has been established. With regard to insanity, there is still diversity of view, and probably much greater actual ignorance, among medical men. A discussion of this subject by Dr. Henry R. Stedman (*Journal of Nervous and Mental Diseases*, January, 1889) is therefore timely.

It is impossible to formulate as yet any definite rules regarding this subject. Alienists at present differ extremely in their views as to the importance of the hereditary element in insanity, perhaps because this element varies enormously with different types of the disease; while it has almost nothing to do with general paresis or puerperal insanity, for example, it has a most dominant influence in epileptic, hysterical, paranoiac, and other forms which are the expressions of a continuous neurotic condition.

When a parent has suffered from puerperal, traumatic, syphilitic, or any form of insanity due to accidental or extrinsic causes, the child, if born before the insanity, can, as a rule, safely marry. Alienists are agreed also that the children of general paretics born before the onset of the disease are safe.

It is claimed, with more confidence, perhaps, than facts justify, that the mother oftener transmits insanity than the father. Hence insanity on the maternal side carries with it greater danger to the offspring.

Richarz gives the following order of liability to insane inheritance:

Mother	insane,	1,	the	daughter	resembling	mother.
"	"	2,	"	son	"	"
"	"	3,	"	daughter	"	father.
"	"	4,	"	son	"	"
Father	"	5,	"	"	"	"
"	"	6,	"	daughter	"	"
"	"	7,	"	"	"	mother.
"	"	8,	"	son	"	"

Slight mental taints in the parents are more dangerous if there is an element of consanguinity.

The personal history and physical characteristics of the patient himself must be especially studied. If these reveal anomalies of mind and physical stigmata such as indicate the insane diathesis, marriage becomes a risky experiment. At the same time it often happens that a person having a slight mental taint, if married to a robust, healthy, nerveless partner, may have healthy and even talented children.

The question of marriage becomes additionally difficult when the party desiring it has been insane and recovered. The conscientious physician will rarely find cases in which he is justified in sanctioning marriages. If there has, however, been but one attack, short in duration, due to accidental causes, and from which the patient has entirely recovered, marriage with a healthy person would be comparatively safe.

Dr. Stedman insists wisely upon the serious results that follow when marriage takes place while recovery is incomplete. The children in such cases are almost sure to be idiotic, imbecile, or the victims of some serious nerve-trouble.

PULSATING PLEURISY.

IN the *Archives générales de Médecine* for November and December, 1883, Dr. J. Comby described a peculiar form of pleurisy which he called "pulsatile." He reported several cases with autopsies, and collected observations by others. In the same journal for April, 1889, this author reviews the subject again, and completes its bibliography, except that, if we mistake not, he has overlooked some American contributors to this subject.

Pulsating pleurisy is a form of pleural inflammation in which, along with the effusion, there is a pulsation of the chest-wall synchronous with the heart-beat. It occurs, naturally, almost always upon the left side; and as the pleurisy is, with very rare exceptions, purulent, it might be properly called pulsatile empyema. The establishment of the fact of a pulsation is, therefore, a clinical fact which has some practical diagnostic importance. The pulsation is often feeble and likely to escape observation unless special care is taken in examining the patient. Its appearance at first suggests aneurism, but the other physical signs quickly exclude this possibility. Pulsatile pleurisy is chronic in its course and characterized by abundant effusion, with compression of the lung. Occasionally only is the effusion small in amount. It is then encysted, and forms special relations with the pericardium and its contents, by reason of which the heart's pulsations are transmitted to the chest-wall. In all cases, according to Comby, there is present at some time in the course of the disease a latent pneumothorax. There is no metallic tinkle, or amphoric souffle, but a tympanitic resonance and succussion-bruit that are easily detected.

The heart is generally healthy, but not rarely one finds some pericardial effusion.

The disease begins abruptly, as an acute pleurisy, and the pulsatile character does not appear until later. The course is very chronic, and some cases have been reported as lasting three and even seven years. The prognosis is, however, bad; most of the patients have died.

"Pulsation" in a pleurisy, as may be seen, is a physical sign that gives important information both as to diagnosis and prognosis. The theory of its production is still a matter of speculation. It is not due to the association of pericardial effusion with pleurisy, as Traube thought. Comby found, in three autopsies, that the lung was

flattened, and attached closely by inflammatory adhesions to the pericardium. There is thus a continuous mass of fluid from the pericardium to the thoracic wall, through which vibrations might easily pass. Besides this, the intercostal muscles are stretched and their functions arrested.

These factors seem to us to explain in a great measure the mechanics of the pulsation.

The treatment of pulsatile pleurisy presents nothing different from that of ordinary chronic empyema. The frequent presence of a pneumothorax has, however, to be borne in mind in the operation of evacuating the fluid.

THE AMERICAN POSTURE.

THESE are the days when even the most ordinary and apparently inconsequential items in human conduct or social custom must be submitted to the prying gaze of science. Everything, from the kiss that first accentuates the dawn of love to the painful struggles of parturiency, has to have its analysis and physiological explanation. It seems somewhat strange therefore that, in this alert and eager search for cause and effect, no one has yet attempted to analyze and place on a solid scientific basis the practice of sitting with one leg crossed over the other. This is a custom which, we venture to assert, is distinctly American, and one that has been observed and transmitted with pious care by the average American male for the past two hundred years. Its prevalence may have become somewhat modified by the incursions, during late years, of foreigners with large waists and weak adductors; but the true American still preserves this detail of his birthright with a constancy and obtrusiveness born of a deep sense of its eternal and inherited fitness.

There are certain inferior races of men who also sit cross-legged. But their case is quite different. They abduct the thighs and cross the legs, assuming a more or less fœtal posture, and one evidently connected with a lower degree of ethnical evolution. The monkey sits somewhat in the same style. In the higher and tenser civilization, however, which has unfolded beneath the stars and stripes, and the ennobling influences of the spoils system in politics, there is nothing fœtal in the posture, but directly the reverse. The adductors of the thighs are brought into play, a nobler group of muscles and one whose superactivity must, we take it, mean a higher physical development of man.

The conditions of life in America made of Brother Jonathan a man with a short trunk, small waist, and long legs, anatomical proportions exactly suited to a comfortable sedentation with the thighs crossed. This type of man still prevails in New England, the South, and parts of the Middle States and the West. With these a posture in which the thighs cross is instinctive. The observations of physiologists and physicists would undoubtedly show that in this position the centre of gravity is thrown forward so that it corresponds more nearly with the tubera ischiorum, thus enabling the sitter to gain a firmer hold upon the seat. Besides this, the weight of the crossing leg doubles the pressure of the foot upon the floor, and this again helps to prevent slipping forward. Whether there is anything in the posture which arouses a particular sense of ease, comfort, and feeling of well-being and contentment, despite a frowning environment, we cannot say. For the American leg-crosser does sometimes carry his habits to extremes. It may require another century of evolution to inoculate those given to the habit with altruism, and teach them that a deeper and truer joy may flow from not wiping their shoes on passing strangers than comes even from the highly evolved muscular adjustments of sitting with superimposed knees.

OUR COLORED PLATE ILLUSTRATING MEASLES.

IN this issue we continue a series of artistic delineations of the commoner forms of eruptive fevers, which are taken from Dr. Morrow's admirably illustrated *Atlas of Cutaneous Diseases*. The first of these, which appeared last month, represented a case of scarlet fever with a well-marked and characteristic general rash, showing, as well as possible by this means, the papillary elevations at different points. The enlarged papillæ of the tongue, with the yellowish-gray coating of the organ, illustrated in a striking manner the typical strawberry appearance to which reference is so frequently made in the text-books. It is not our purpose in these representations to do more than give the actual clinical aspect of a patient, referring our readers to the treatises on the subject for detailed study. The present one illustrating common measles, needs but to be referred to to be appreciated. At stated intervals will follow illustrations of German measles and small-pox. Aside from their clinical accuracy, these plates will be valued for their artistic excellence, as their equals in the latter respect have never been possible before in the heavy presswork of thousands of issues.

EXPLORATION OF THE BRAIN BY CAPILLARY HOLES.

DR. EDMOND SOUCHON, of New Orleans, in an article in the *New Orleans Medical and Surgical Journal*, describes an ingenious method of exploring the brain without trephining the skull. His procedure is as follows: A small incision is made in the scalp as far as the bone. Through this incision the bit of a watchmaker's drill was introduced, and as soon as it had reached the bone the instrument was held firmly pressed against the bone, and the sliding knot of the instrument worked, at first slowly, then swiftly, and again slowly as the bit penetrated the bone and came near the brain-substance. The bit is provided with a movable gauge and screw, which is adjusted so as to prevent the bit from penetrating too deeply into the brain-tissue.

As soon as the skull has been penetrated the drill is withdrawn and a hypodermic needle with syringe introduced. The needle should be twice as large as the ordinary needle of our cases, so that, if it should strike the thick pus of an abscess or the thick fluid of a cyst, the calibre will be large enough to suck it—which it will surely not do if the needle is as fine as the one ordinarily used for a hypodermic injection.

Two dogs were experimented upon, and holes were bored in six places without producing any unfavorable symptoms. On subsequently killing the animals, no injury was found to have been done aside from the production of a very small superficial hemorrhage. This possibility of hemorrhage is one that will probably limit the usefulness of the operation.

THE TEETH AND THE GENERAL PRACTITIONER.

AFFECTIONS of the teeth are not so often considered in our columns but that the general practitioner may congratulate himself on the appearance, in this issue, of an instructive, though cursory, paper and discussion on this subject before a recent meeting of the Practitioners' Society of New York. There is doubtless a strongly rooted reluctance on the part of the profession (and this was brought out in the discussion to some extent) to agree with the writer in respect to the importance he attaches to the dental reflex. But the candid observer can but feel that much careless dental work may be the outcome of referring dental neuroses due to caries of the teeth for treatment to persons unfamiliar, as most dentists are, with the important relations of the teeth with other organs. And where the physician is unable himself to offer any suggestions to the dentist in this regard, the patient is liable to be made worse rather than better, especially from the practice of saving so-called dead teeth. We trust the interest excited by thus bringing this subject before the profession may continue until the surgical importance of diseases of the teeth is recognized by medical men. Every surgeon now fully recognizes the importance of drainage and antisepsis in the treatment of necrotic processes, especially of the osseous tissues; and unless better means than now generally prevail—since the above well-known surgical principles are ignored in treating "dead" teeth so as to retain them in the jaws—are adopted, more or less danger is imminent in every case where the attempt is made.

TAR-WATER.

THIS once famous remedy, first recommended by the Bishop of Cloyne over one hundred years ago, has in late years been but little employed. Some recent contributions to the subject, however, appear likely to bring it again into more general use.

Tar-water, made from wood-tar, contains about thirty grains of the drug to a quart. Chemically, the substances in solution are said to be pyroligneous acid, an empyreumatic oil, and creasote. The liquid has a pungent taste, a smoky odor, and acid reaction. Locally it is unirritating, and slightly astringent and stimulating. Dr. Joseph E. Allen has recently recommended its use (*Atlanta Medical and Surgical Journal*) in obstetrical and gynecological practice. It forms an excellent antiseptic injection in the puerperal state and in cases of leucorrhœa and vaginitis, as well as in pruritus vulvæ. Skene has recommended it, taken internally, in chronic cystitis, and it may also, according to Dr. White, be used as an injection into the bladder.

Bishop Berkeley said of tar-water: "Having tried it in a great variety of cases, I found it succeed beyond my hopes; in a tedious and painful ulceration of the bowels, in a consumptive cough (as appeared by expectorated pus), an ulcer of the lungs, in a pleurisy and peripneumony. I never knew anything so good for the stomach as tar-water, it cures indigestion and gives a good appetite. It is an excellent medicine in asthma. It imparts a kindly warmth and quick circulation to the juices without heating, and is therefore useful not only as a pectoral and balsamic, but also as a powerful and safe deobstruent in cachectic and hysteric cases. As it is both healing and diuretic, it is very good for the gravel. I believe it to be of very great use in a dropsy."

Dr. William Murrell has recently delivered a lecture upon the therapeutic value of tar, and has gone very thoroughly into the history of its uses. He refers to a pamphlet, written in 1823, by Sir Alexander Crichton, entitled "Practical Observations on the Treatment and Cure of Several Varieties of Pulmonary Consumption, and on the Effects of Vapor of Boiling Tar in the Disease;" also to an article by Sales-Girons, in 1860, on the treatment of phthisis by inhalation of pulverized liquids and fumigations of tar. Dr. Murrell has been using tar in the treatment of chronic bronchitis, and speaks of it in the highest terms. He at first used two-grain pills, but has latterly prescribed the syrupus picis liquidæ U. S. P., of which the dose is about a tablespoonful, given frequently. He says: "A mixture of two parts of sirup of tar and one part of sirup of Virginia prune is an ideal cough-mixture. It has a sweet, agreeable taste, and patients, as a rule, like it. When the cough is very irritable, and there is very little secretion, the addition of three minims of liquor morphinæ acetatis will be found most useful. I have used with some success aromatic oil of tar, which is apparently a solution of tar in old Jamaica rum. The results have been good, and the preparation is popular with patients. When a more decided expectorant action is required, I add a small dose of hydrochlorate of apomorphine, about one-tenth of a grain."

IMPROVED TREATMENT FOR TINEA TONSURANS.

ALTHOUGH in most cases this disfiguring disease yields readily to one or other of the many applications which are recommended for it, yet in some cases, as the physician knows to his grief, it proves extremely obstinate, and the wisest efforts serve only to suppress it for a time. Some years ago Dr. Harrison, of Bristol, attempted, in a paper before the British Medical Association, to lay down more clearly the principles upon which successful treatment must be based. He showed that two sets of agents were needed: the first, an agent to dissolve the hair and to expose the fungus in its lurking places in the cuticle, hair, and hair-follicles; the second, a parasiticide to destroy the fungus. For the first he recommended a solution composed of liquor potassæ, spirits of wine, and iodide of potassium; for the second a solution of mercuric chloride in spirits of wine and water. By this method, through the softening action of the alkali, the iodide of potassium was allowed to soak into the parts affected, and then the application of the mercuric solution formed the very excellent parasiticide, biniodide of potassium, in and about the tissues occupied by the fungus. In the *British Medical Journal*, March 2, 1889, he presents a simpler plan, in which the drugs are applied in the form of ointment. He finds that patients will carefully rub in an ointment, when they will not take the trouble to properly apply a solution. The ointment which he uses is made a follows: Caustic potash, gr. ix.; carbolic acid, gr. xxiv.; lanolin and oil of cocoa-nut, of each, ʒ ss. The ingredients must be well rubbed together, and a little oil of cloves, lavender, or rosemary may, if desired, be added. A small portion of the ointment is to be rubbed on the affected part, night and morning. The alkali softens the hair, and allows the carbolic acid (it

WILLIAM WOOD & COMPANY, Publishers, NEW YORK

LINDNER, EDDY & CLAUSS, LITH. N. Y.

should be remembered that carbolic acid is not an acid, and does not combine with alkalies) to reach and destroy the fungus. He thinks it is better not to shave the part, but to leave the hair at least a fourth of an inch long, as the ointment is then kept upon the part.

To prevent infection from ringworm of the scalp, he employs an ointment of the following composition: Ointment of boracic acid, and ointment of eucalyptus, of each ℥ ij.; oil of cloves, 3 ss.; oil of cocoa-nut, enough to make ℥ vj. This, he says, constitutes a very elegant pomade even for general use, and is also an excellent prophylactic pomade. When ringworm makes its appearance in a family, he recommends that this prophylactic pomade be applied daily, not only to the healthy parts of the patient's scalp, but also to the heads of the other children in the family. To test its protective powers he has in three cases placed infected hairs on the heads of healthy children, and then first applied the pomade on the next day. None of the children caught the disease. The great confidence which he feels in the efficiency of the methods described above is founded upon the observation and treatment of more than one hundred cases of tinea tonsurans.

News of the Week.

An International Congress of Medical Jurisprudence will be held in this city, June 4, 5, 6, and 7, 1889.

State Medical Society of Wisconsin.—The next meeting of the Society will be held in Milwaukee, commencing Tuesday, June 4th.

Pennsylvania State Medical Society.—The Thirty-seventh annual session of the Pennsylvania State Medical Society will be held in Pittsburg, June 4th to 7th.

The Emanuel Sisterhood of Personal Service, of New York, has been incorporated. Its object is to direct and aid its members who desire to devote a portion of their time to visiting the sick and caring for young children.

The Missouri Pacific Railway Hospital at Independence will soon be removed to Kansas City. Temporary quarters have been secured at the corner of Sixteenth and Penn Streets; but it is the intention of the road, as soon as a suitable site can be secured, to erect a $40,000 building for the hospital.

Dr. Henry E. Allison, first assistant at Willard Asylum since 1878, was appointed Medical Superintendent of the New York State Asylum for Insane Criminals at Auburn, by Superintendent of Prisons Lathrop, to-day. Dr. Allison succeeds Dr. Carlos F. Macdonald, who has been appointed on the new State Lunacy Commission.

Indiana Physicians.—At a recent meeting of the Indiana State Medical Society, Dr. J. F. Hibbard, of Richmond, stated that there are 4,163 registered physicians in that State. Of these, 3,243 are regular physicians, of whom about 1,300 are members of the State Medical Society; 287 are classed as eclectic; 199 as homœopathists; 142, physio-medical; and 192 are unclassified.

A New Medical College has been organized at Knoxville, Tenn.

The Fourth Annual Dinner of the New York Postgraduate Medical School was held at the Hotel Brunswick on Thursday, May 23, 1889. Dr. D. B. St. John Roosa, President of the Faculty, occupied the head of the table and introduced the speakers in his characteristically felicitous manner. The toasts were responded to as follows: "The Faculty," by Professor Charles Carroll Lee, M.D.; "The State of New York," by Hon. William H. Robertson; "The Clergy," by Rev. David H. Greer, D.D.; "The Profession in New York," by Professor T. Gaillard Thomas, M.D.; "Our Directors," by Professor Andrew H. Smith, M.D. Dr. C. C. Rice, the Secretary of the Faculty, spoke of the prosperity of the school, the large class that had been in attendance last year, and stated that the school now owned its building, a fact which was received with becoming enthusiasm. Among the other features of the evening was an admirably apt poem by Professor Charles L. Dana, and remarks by Judge Haws and Mr. Russell Harrison.

The Johns Hopkins Hospital.—The following is the staff of the hospital: Physician-in-chief—Dr. William Osler; Pathologist—Dr. W. H. Welch; Chief of Dispensary—Dr. W. S. Halsted; Resident House Physician—Dr. H. A. Lafleur; Resident House Surgeon—Dr. F. J. Brockway; Assistant House Physician—Dr. Harry Taulmin; Assistant House Surgeon—Dr. G. E. Clarke; Consulting Physicians and Surgeons—Dr. Alan P. Smith, on the part of the hospital trustees, and Dr. James Carey Thomas, on the part of the university trustees, and Drs. Isaac E. Atkinson, S. C. Chew, Frank Donaldson, W. T. Howard, C. Johnston, T. S. Latimer, F. T. Miles, G. W. Miltenberger, L. McLane Tiffany, and H. P. C. Wilson. Staff of Dispensary—Chief of Surgeons, Dr. W. S. Halsted, with the assistance in general surgery of Drs. James Brown and J. M. T. Finney, and the resident house surgeon, with Dr. S. Theobald in charge of the department of diseases of the eye and ear, and Dr. R. B. Morison in charge of the department of diseases of the skin. Chief physician, Dr. W. Osler, with the assistance of Dr. William D. Booker, in the treatment of diseases of children, and Dr. H. M. Thomas in the treatment of nervous diseases, and the resident house physicians, with Dr. J. N. Mackenzie of the department of the diseases of the throat.

A Memorial Hospital for Railroad Men.—The memory of Thomas J. Potter, one of Iowa's most noted railroad men, will be perpetuated by a hospital for injured and sick railroad men, instead of by a bronze statue of heroic size, as was planned at the time of his death, about a year ago. Mr. Potter was Vice-President and General Manager of the Chicago, Burlington & Quincy road, and such a hospital as is contemplated was one of his favorite projects.

The New Cure for Constipation.—Dr. Clement Cleveland's interesting paper on stretching the sphincter as a cure for constipation, which recently appeared in The Medical Record, has commanded a great deal of attention at home and abroad, having been extensively quoted and abstracted. We should like to know what they will think of it in Turkey.

Society Reports.

THE AMERICAN SURGICAL ASSOCIATION.

Annual Meeting, held in the New Army Medical Museum, Washington, May 14, 15, and 16, 1889.

(Continued from page 587.)

SECOND DAY, WEDNESDAY, MAY 15TH — AFTERNOON SESSION.

THE first paper, read by DR. THEO. A. MCGRAW, of Detroit, was entitled

A CONTRIBUTION TO THE HISTORY OF GUNSHOT WOUNDS OF THE ABDOMEN.

Reference was first made to a case of gunshot wound of the abdomen, operated on by Dr. R. Abbe, of New York, July 8, 1886, in which, four hours after the accident, adhesions of the intestine to the abdominal wall were found, forming a cavity containing extravasated fæces. The adhesions were broken up, and four holes in the bowel and one in the bladder were closed. Suppression of urine and death followed. In August, 1887, the author was called to a case of gunshot wound of the abdomen, fourteen hours after its occurrence. At the operation it was found that adhesions had formed, shutting off the peritoneal cavity. These were broken up and eight perforations of the bowel found. Five of these had become so occluded by lymph as to be detected with difficulty and no discharge could be forced through them. Four feet of the ileum was excised. The patient died twenty-six hours after the operation. A study of these cases led the reader to suggest that under such circumstances the drainage of the cavity would be the best plan to adopt. The artificial anus or fecal fistula could then be operated on at a later period. The question arises whether or not these cases of early agglutination are sufficiently numerous to warrant our making them the point on which the treatment of all cases of penetrating wounds of the abdomen over six hours old must turn This question cannot be decided at present.

A review of the approved methods of treating gunshot wounds of the abdomen was then taken up. The great danger has been shock. The shock has depended, first, upon the time occupied in operating; second, upon the amount of evisceration; third, upon the number and the nature of the injuries to be repaired; fourth, upon the chilling of the intestines, and fifth, possibly upon the long continued anæsthesia. In discussing the subject the following propositions were considered—many of them based upon experiments upon dogs and sheep.

1. The gravity of an injury of this kind depends partly upon the size of the missile.

2. Gunshots which enter the abdominal cavity pass in a nearly absolutely straight line from the orifice of entrance, through the peritoneum to that of exit or to their final stopping-place in the viscera. All apparent deviation of bullets fired into the abdomen from a direct path are due to changes in position subsequent to the shooting.

3. An incision made directly in the course of the ball will give the shortest route to the injured viscera.

4. The contents of the bowels may be made to discharge through an open gunshot wound by manipulation and pressure.

5. An empty condition of the alimentary canal is most favorable to healing. To secure this it may be proper, in some cases of injury of the bowel, immediately after a hearty meal to evacuate the contents of the stomach by means of a siphon.

6. Agglutination and limitation of the morbid processes consequent upon gunshot wounds may take place as early as the sixth day.

7. Senn's method of hydrogen gas insufflation, however admirable in recent cases, should be used with great caution in cases four hours old, and especially in those made by small bullets.

8. The dangers of the operations for penetrating gunshot wounds of the abdomen are directly in proportion to the length of the operation and to the amount of the evisceration. The duration of the operation may be lessened: 1st, by making the incision over the line taken by the ball, or, if it has passed from before backward, over the point of entrance; 2d, by limiting the examination of the viscera strictly to such of them as may have been in the course of the ball; 3d, by suturing wounds of the intestine, whenever it is possible, instead of excising them; 4th, by omitting all operative procedures, even suture in wounds which have become so thoroughly occluded by plastic material that the contents of the bowel cannot be pressed through them; 5th, by operating first on those wounds which imperatively demand it, and leaving to the last those which may recover without operation; 6th, by never eviscerating a patient, except, first, when hemorrhage is otherwise uncontrollable, and second, when there is evidently a discharging wound which cannot otherwise be found. The evisceration of a patient is as dangerous as any gunshot wound of the intestine which cannot be made to discharge its contents by manipulation or pressure can possibly be. There are cases when evisceration is necessary, but the author protested earnestly against the habit of eviscerating patients suffering from gunshot wounds of the abdomen as a matter of routine. We are not warranted in turning a man inside out and subjecting him to frightful dangers in the mere fear that there may be still an undiscovered wound, when all the symptoms which ought to indicate such a wound are absent.

9. In cases of these wounds in which patients may be too weak to endure any radical operation for their repair, efforts for their relief may be made by incision and drainage, and in some cases by attaching the injured intestines to the abdominal wall as in gangrenous hernia. This procedure occupying but little time, and making no draft upon the strength of the patient, may offer a hope of recovery which would not be possible under the expectant mode of treatment.

DISCUSSION.

DR. D. W. YANDELL, of Louisville: The statement in regard to the course of balls is new to me. A number of cases which I have seen had led me to believe that balls entering the abdomen might deviate very greatly. I am not altogether prepared to accept the statement at present. In one case in which the pistol was held near the individual, and in a straight line, the ball entered above the symphisis pubis and was found below the spleen, having wounded intestines in its course.

The recommendation that, in the extreme cases where the patient is greatly exhausted, the wounded intestine be secured at the abdominal incision, is certainly conservative, and it would seem to me to be wise.

DR. C. B. NANCREDE, of Philadelphia: There are such a number of cases on record in which it was supposed that the balls were reflected, that I think that there can be no doubt that this occurs occasionally.

In regard to the incision: From my experience with both the median and the lateral incision, I am forced to the conclusion that, unless we are certain that the ball has followed an antero-posterior course, the median incision is to be adopted in every case, with rare exceptions.

I suppose that Dr. McGraw means by evisceration removal of the intestines *en masse*. It makes a great difference, as far as shock is concerned, whether the intestines are removed all together, or simply an inch brought out of the opening, immediately replaced, and another portion examined, at no time exposing a large portion of the bowel. So many cases have been recorded in which death was the direct result of overlooking a single wound of the viscera or blood-vessels, that the only safe rule is to make a thorough examination before closing the abdominal incision.

DR. J. EWING MEARS, of Philadelphia: The median incision is, I think, the one which should be adopted. It

can be extended any desired distance, which cannot be done with the lateral incision. By the median incision the entire abdominal cavity can be inspected.

In regard to what has been termed evisceration, I think that it is better to permit the patient to die without operation, than that an incomplete or imperfect operation should be performed. I think that the surgeon would be almost criminally culpable if, after subjecting the patient to the dangers of an abdominal section, he closed the abdomen without satisfying himself by thorough examination that he has found every wound that could have been inflicted. It is not necessary to turn all the intestines out. It is sufficient to slip them through the hands, subjecting them to careful inspection.

Dr. R. A. Kinloch, of Charleston: After the abdomen is opened in a search for wounds, I think that every wound should be closed. We cannot say that one wound is of less importance than another.

Dr. W. W. Keen, of Philadelphia: As regards the line of incision, we should make a distinction between stab-wounds and gunshot wounds. In the former case I think the incision should be made at the point of wound, while in the latter the almost invariable rule should be the median incision. I can but agree with previous speakers that, after we have opened the abdomen, no case is properly treated if we leave by any possibility a single wound. Every wound should be sutured.

Dr. C. H. Masten, of Mobile: In regard to the course of balls, I treated one case in which the ball entered one inch to the right of the umbilicus, made nine openings in the intestine, passed down through the bladder, out through the prostate, and lodged near the tuber ischii on the left side. The spinal column had not been injured.

Dr. F. S. Dennis, of New York: I believe that it is a rule without exception that the median incision should be made where we are going to sew perforations in the bowel, or stop hemorrhage in the abdominal cavity. The point of first importance is the control of hemorrhage. The median incision will permit the surgeon to enter the peritoneal cavity in half a minute.

Dr. Stephen H. Weeks, of Portland, Me.: I have not heard allusion in regard to the use of Dr. Senn's method. He laid stress upon two points, first, the use of gas in determining whether perforation had occurred, and second, in locating the openings in the bowel. It seems to me that this latter is a valuable point.

Dr. Stephen H. Weeks read a paper entitled

DRAINAGE AND DRAINAGE-TUBES IN THEIR APPLICATION TO THE TREATMENT OF WOUNDS.

The paper first referred to the great importance of drainage, and after alluding to the various methods proposed for securing it, described a new form of absorbable drainage-tube prepared from the arteries of animals. The arteries used are those of the ox. They are separated from their sheaths and cut into tubes four or five inches long. They are then boiled in water for about five minutes. This sterilizes them and hardens their coats. Holes are next cut in their sides, and they are passed over glass rods of different sizes according to the size of tube desired. They are now placed in corrosive sublimate solution, one to one hundred, and allowed to remain ten minutes. Then they are placed in alcohol, ninety-five per cent., and at the end of twenty-four or forty-eight hours the glass rods are removed, the tubes being kept in alcohol until needed. These tubes are unirritating to the tissues; they are absorbed in from five to seven days and drain the wound perfectly.

Adjourned.

Third Day, Thursday, May 16th—Morning Session.

Dr. John Homans, of Boston, read a paper on

A SUCCESSFUL CASE OF NEPHRECTOMY FOR THE REMOVAL OF CANCER OF THE RIGHT KIDNEY.

The patient, a woman aged fifty, for a year had suffered with frequency of micturition. The urine had been dark and bloody at times. For three years she had suffered from indigestion. The tumor had been discovered in 1887, in the right iliac region, and since July, 1888, it had grown rapidly. It filled the right iliac region, and more or less the umbilical and pubic regions. On palpation, large irregular nodules were felt, and in some parts there was fluctuation. Laparotomy was performed January 21, 1889. The incision was made in the linea alba, and was four inches in length. The tumor was exposed, and in the upper part was seen the remaining portion of the kidney and two large renal veins. These were tied with silk, and the ureter was next tied and divided, and then the pedicle was readily ligated. The tumor was removed, a glass drainage-tube introduced, and the wound closed and dressed with iodoform gauze and absorbent cotton. The tumor measured six by nine inches, and weighed fifty-three ounces. There was very little shock. The amount of urine since the operation has varied between ten and fifty-seven ounces, and has been gradually increasing. There was but little discharge from the drainage-tube, which was removed on the fourth day. One month after the operation an abscess was opened in the right lumbar region. A slight swelling and some tenderness still remain in the right loin. Whether these are wholly inflammatory or due to a recurrence of the growth, cannot at present be determined. The patient is rapidly gaining strength.

The experience of the author led him to say that a large renal tumor which cannot be diminished in size by tapping (he would consider one weighing a pound or more a large tumor), can most conveniently be removed by an incision through the linea semilunaris or in the linea alba. Small tumors and those that can be diminished, may be removed by the lumbar incision. In cases of moderate-sized kidneys, disorganized with pus, or tubercular, or containing calculi, the lumbar incision is preferable.

Dr. Frederick E. Lange, of New York: In cases where a large tumor of the kidney is to be removed, and where it is desirable not to open the peritoneal cavity, I have found a trap-door incision with exsection of one or two ribs, if necessary, give ample room for operation. I have operated nine times, but never for neoplasm. With free incision and open antiseptic after-treatment, I regard extirpation of the kidney, even in cases of large tumors, a comparatively safe operation.

Dr. M. H. Richardson, of Boston: There is a frequent anomaly of the vascular supply of the kidney which should be borne in mind in operations. Instead of one renal artery, there may be three or even four arteries. If such a pedicle is ligated en masse there is danger of slipping of the ligature and hemorrhage. This is obviated by tying the pedicle in several sections.

Dr. Lewis S. Pilcher, of Brooklyn, read a paper on

THE QUESTION OF THE ANTITUBERCULAR POWER OF IODOFORM, WITH A SUGGESTION FOR A MORE EXACT CLINICAL TESTING OF THE SAME.

The paper first called attention to the different results obtained by the application of iodoform to tubercular tissues, according as the results were derived from clinical experience or from observation on tubercular affections artificially induced in animals. The following case was a contribution to the study of this question.

A girl, thirteen years of age, with a family history of tuberculosis, came under observation with an infiltrated and ulcerated patch on each leg. There was also on each thigh an infiltrated patch without ulceration. The disease was of three months' standing. The diagnosis of tuberculosis of skin was made. The patch on the right leg was excised, and microscopical examination confirmed the diagnosis; tuberculous nodules with bacilli were found. The patches on the thighs were also excised, and healed without further treatment. Bismuth was applied to the patch on the right leg, and healing progressed satisfactorily. It was then determined to apply skin-grafts. The sore was curetted, the grafts applied, and did well for a time.

Later the epithelial elements broke down and a number of small ulcers formed. At the base of each ulcer was found a particle of bismuth. Portions of the tissue removed, however, showed no bacilli. No iodoform had been employed. Boracic acid ointment and the occasional application of nitrate of silver were now ordered. The ulcer on the left leg was curetted on December 10, 1888, sprinkled with iodoform, and covered with absorbent cotton. It rapidly healed, and on January 25th a wedge-shaped piece was removed and examined. It was entirely free from evidences of tuberculosis. A soft, natural skin has since formed.

Dr. William H. Pancoast, of Philadelphia, made some brief remarks on the following topics:

I. That the so-called metacarpal bone of the thumb did not belong to the metacarpal group; that its method of development clearly placed it in the class with the phalanges.

II. He next exhibited and described his urethrotome, which he had used with satisfaction for twenty years.

III. A delicate knife, which he termed the "therapeutic knife," employed for making numerous minute punctures in an inflamed part for securing an antiphlogistic effect.

IV. A gun-breech, which had remained for some time unsuspected in the superior maxillary bone of a boy.

V. The use of black silk bandages and black adhesive plaster, as adding greatly to the neatness of a dressing.

VI. The use of iron-dyed black silk ligatures.

VII. His method of treating varicocele, by passing a silk thread through the scrotum between the vas deferens and the veins, returning it through the same opening in the skin, but in front of the veins, passing the ends of the ligature through holes in a metal plate and tying tightly. The cure is complete in three or four days.

The Committee appointed to take action in regard to the death of Dr. S. W. Gross presented the following:

Whereas, It has pleased the Almighty to remove from our midst Dr. Samuel W. Gross, who assisted in founding the American Surgical Association, and contributed by his example and work largely to its success; who as a teacher was enlightened and impressive, as an author was accurate and original, as a surgeon was sound in judgment, rich in clinical experience, skilled in manipulation, and as a Fellow was genial and courteous. Therefore, be it

Resolved, That the Association deplores his death as an irreparable loss, and directs that a copy of the foregoing be spread upon its minutes and forwarded to his bereaved family.

(Signed)
D. W. Yandell, P. S. Conner, J. Ewing Mears.

OFFICERS FOR ENSUING YEAR.

President—Dr. D. W. Yandell, Louisville, Ky.; *Vice-Presidents*—Dr. Claudius H. Masten, Mobile; Dr. C. B. Nancrede, Philadelphia; *Secretary*—Dr. J. R. Weist, Richmond, Ind.; *Treasurer*—Dr. P. S. Conner, Cincinnati; *Recorder*—Dr. J. Ewing Mears, Philadelphia; *Council*—Drs. John S. Billings, L. McLane Tiffany, W. F. Peck, and F. S. Dennis; *Chairman of Committee of Arrangements*—Dr. J. S. Billings, Washington.

The following were elected members: Dr. Stephen H. Weeks, Portland, Me.; Dr. Robert F. Weir, New York; Dr. John Homans, Boston; Dr. Lewis A. Stimson, New York; Dr. Frederick E. Lange, New York; Dr. Lewis S. Pilcher, Brooklyn; Dr. Levi Cooper Lane, San Francisco; and Dr. Arthur T. Cabot, Boston.

The Association then adjourned, to meet in Washington the second Tuesday in May, 1890.

He Charges Five Dollars for Thrown Kisses.—One of the most fashionable of Philadelphia physicians always kisses his hand when waving farewell to his wealthiest lady patients; but some of them were comparing notes the other day, and found that for visits when he kissed his hand he charged ten dollars, while for others he charged only five.—*Philadelphia Times.*

THE NATIONAL ASSOCIATION OF RAILWAY SURGEONS.

Second Annual Meeting, held in St. Louis, Mo., May 2 and 3, 1889.

First Day, Thursday, May 2d—Morning Session.

The Association met at the Pickwick Theatre, and was called to order by the President, Dr. J. W. Jackson, of Kansas City, at 10.30 A.M.

The Rev. S. J. Nicolls, of the Congregational Church, of St. Louis, offered prayer.

Mayor Noonan, who was to have delivered the address of welcome, was unable to be present, and sent his regrets.

The address on behalf of the local profession was delivered by Dr. E. L. Gregory. He said the splendor of modern surgery comes to wipe away the shame of mutilation, once so humiliating in railroad injuries. The discovery of the causes of inflammation and the methods of prevention have revolutionized medical science. Amputation, once the rule, was now the exception. Life in a limb is now a guarantee of its preservation.

Dr. J. H. Murphy, of St. Paul, Minn., followed Dr. Gregory with some timely and appropriate remarks.

Dr. J. B. Murdock, of Pittsburg, Pa., contributed a paper entitled

TORSION OF ARTERIES FOR THE ARREST OF HEMORRHAGE,

in which he said, upon no subject has our profession been more conservative than upon the manner of arresting hemorrhage after wounds of the arteries and veins. Since the time of Celsus, notwithstanding the numerous methods which have been proposed for this purpose, but two, viz., the actual cautery and the ligature, have received the endorsement of the profession. But if the profession has been slow to endorse new methods, its confidence once gained has not been easily shaken. This could be illustrated by the tenacity with which surgeons adhered to the use of the actual cautery after the discovery of the ligature. The twisting of an artery to arrest bleeding is of ancient origin. It has been advocated by such surgeons as Amusset, Diffenbach, Schroeder, and Syme. But the credit of bringing it prominently before the profession and establishing its efficiency is due to Bryant, the present distinguished surgeon of Guy's Hospital, London. At this hospital the ligature is seldom used, torsion being chiefly relied upon. Mr. Bryant tells us, in the last edition of his "Surgery," that in 200 consecutive amputations of the thigh, leg, arm, and forearm, all of the arteries were twisted, 110 of them being the femoral artery, and that in no case was there secondary hemorrhage. At the Western Pennsylvania Hospital, of Pittsburg, torsion is almost exclusively relied upon to check the hemorrhage from wounded arteries or veins. Dr. Murdock's experience with torsion as a hæmostatic dates back to the year 1872, when he became a member of the hospital staff, and for the past fourteen years he has not had a case of secondary hemorrhage which could be fairly attributed to torsion. A table showing the number of arteries divided, in cases of amputation where torsion has been resorted to for the arrest of hemorrhage, at the Western Pennsylvania Hospital, is as follows:

Femoral	95	times.
Popliteal	14	"
Axillary	15	"
Anterior tibial	276	"
Posterior tibial	276	"
Brachial	62	"
Radial	40	"
Ulnar	40	"
Total	818	"

The advantages of torsion as compared with ligation are:

1. The greater facility with which it can be applied. He was fully aware that this proposition is disputed, but

to those who are familiar with both methods there can be no doubt that torsion is the easier of the two. For the ligation of an artery an assistant is required to seize the vessel and draw it out while the ligature is applied. For torsion the surgeon requires no assistant. The vessel must be seized by the forceps in either case. In torsion it only requires three or four turns of the forceps to complete the process, which can be accomplished in as many seconds.

2. Torsion is a safer method, being less liable to be followed by secondary hemorrhage.

3. Healing is facilitated, because the wound is free from any irritating or foreign body.

Dr. A. S. von Mansfield, of Ashland, Neb., understood the essayist to say that the animal ligature is not as safe as torsion. He would hold that the ligature does the same thing that torsion does in arresting hemorrhage. It destroys the intima of the vessel, and as a consequence coagulation takes place.

Dr. George A. Baxter, of Chattanooga, Tenn., desired to say that Dr. Battey, of Rome, Ga., had abandoned the animal ligature entirely, claiming its absorption is too quick, and its danger of unbinding too liable to make it serviceable in important operations. If this is true, he should say torsion is the more preferable of the two.

Dr. S. D. Robbins, of Vicksburg, Miss., asked whether torsion could be resorted to in an artery so important as the femoral, instead of ligation, with equally as good results.

Dr. Murdock replied, Yes; he had applied torsion in the case of the femoral artery ninety-five times with success.

Dr. Good, of Birmingham, Ala., would not abandon the ligature entirely for torsion, but would draw the line in certain cases.

Dr. P. French, of Mexico, Miss., had seen Bryant apply torsion, and in order that the members might have a correct understanding as to the number of twists or turns, he would say that Bryant recommends making turns until the surgeon feels a want of resistance in the vessels.

Dr. W. A. McCandles, of St. Louis, held that the pedicle of tumors and the catgut ligature became living tissue.

Dr. S. S. Thorn, of Toledo, O., arose and refuted the remarks of the preceding speaker. According to experimentation they were absorbed. We have evidences of this in operations where the ligature is used in closing surface wounds.

Dr. G. J. Northrop, of Marquette, Mich., desired the essayist, in closing the discussion, to state in what cases he would apply torsion, and what cases he would select for the ligature.

Dr. R. Harvey Reed, of Mansfield, O., said the question of what becomes of a ligature in ligating vessels had been pretty thoroughly demonstrated by experimentation. Dr. Senn, of Milwaukee, Wis., had demonstrated that it was absorbed in experimenting on animals. The silk ligature, however, becomes encysted in from twenty to thirty days after the animal is killed. He had himself demonstrated this by experimentation. In the use of the catgut suture in abdominal surgery, unless the closure of the wound is rapid, the catgut becomes absorbed. He had never known the silk ligature to become absorbed and fail to do its duty.

With all due deference to Dr. Murdock, he was a little afraid of torsion. He had experienced little or no difficulty with antiseptic silk sutures.

Dr. Nye, of Pennsylvania, asked whether Dr. Murdock had an opportunity of examining an artery several days after he had applied torsion to know its condition.

Dr. J. H. Murphy, of St. Paul, would hereafter try torsion, and after he did that he would apply a silk ligature as a means of further safety.

Dr. Murdock, in closing the discussion, said it matters not whether torsion or ligation be resorted to, the principle is the same. With regard to the twisting of arteries, he finds that it requires four or five, or possibly more, revolutions of the forceps to make the necessary resistance. The surgeon knows that when a ligature is applied to an artery, whether it be silk or catgut, it ruptures the internal and middle coats. It is the external coat that resists tension of the ligature. There is retraction and contraction of the inner and middle coats, and a clot is formed, and it is the final organization of this clot that arrests the hemorrhage.

His reasons in favor of torsion over the silk or catgut ligature are:

1. On account of the greater facility with which it can be applied.

2. If the surgeon uses catgut the knot will untwist; it becomes softened before the clot is organized, and in that case secondary hemorrhage is likely to occur.

3. With the experience of both in Guy's Hospital, London, and the Western Pennsylvania Hospital, it is safer.

Afternoon Session.

The Association reassembled at 2 P.M., with President Jackson in the chair.

Dr. E. R. Lewis, of Kansas City, read a volunteer paper on

THE HOT SPRINGS OF ARKANSAS,

which was referred to the Committee on Publication.

First Vice-President Murphy was called to the chair, and President Jackson delivered his address, taking for his text

THE RAILWAY HOSPITAL SYSTEM OF THE MISSISSIPPI VALLEY.

The address was practically a history of the railway hospital movement, which, according to the speaker's data, originated in the West. The first consideration he had given to the subject of the establishment of a railroad hospital service was in 1867, during his incumbency of the office of local surgeon of the Missouri Pacific, at Kansas City. But there his surroundings forbade making such an attempt, although he did make the effort in 1872, as chief surgeon of the Atlantic & Pacific Railway Company, in a territory extending from Pacific, Mo., to Vinita, Indian Territory, and from St. Louis to Atchison, Kan. His first equipment was crude, and the success of the plan limited, owing to the lack of proper facilities for competent instant attention to persons injured on railroads, as well as for want of subsequent attendance and nursing. It was in the summer of 1879 that Dr. Jackson persuaded Superintendent Talmage, of the Wabash, to make the attempt to establish a railroad hospital service on the assessment plan, which to-day had the almost universal indorsement of not only railway employees, but of the public at large.

A spirited discussion followed the President's address, the arguments being for and against the establishment of such union hospitals.

A copy of the address was ordered to be sent to every railroad manager throughout the country.

The following resolution, offered by Dr. John E. Owens, of Chicago, was adopted without debate:

"*Whereas*, During the past few years there have been organized, in different parts of the United States, several chartered corporations styling themselves, 'The National Benefit Association,' 'The Mutual Aid Hospital Association,' 'The Sanitarium,' and the like, offering, for small considerations, $6 to $10 annually, to issue certificates to members, agreeing to furnish, in the event of sickness or accident, board, lodging, medicine, nursing, medical and surgical attendance; and

"*Whereas*, Contracts have been made, and are being made, with the hospitals in towns and cities throughout the United States, to furnish divers persons, holding the certificates of such associations, board, lodging, nursing, medical and surgical attendance, all necessary surgical instruments, and medicines of the best quality, under such

regulations as the said associations shall from time to time prescribe, for the compensation of $1 per day in wards, or $10 per week in private rooms; and

"*Whereas*, We have already sufficient abuse of charity without permitting the development of another enterprise which thrives at the expense of hospital physicians and surgeons, who, per force of contracts made by said associations on the one hand, and by the hospitals on the other, must turn out at all hours of the night, without compensation, to further the interests of the 'one-man' institution for whose pecuniary benefit the scheme is devised:

"*Resolved*, That the members of the National Association of Railway Surgeons resent this new imposition upon the staffs of the various hospitals; that they acquaint the hospital authorities with the injustice of the scheme, and urge them to refuse such contracts as oblige their fellow-laborers in true charity to render professional services to the above-named benefit associations without compensation."

Dr. W. B. Outten, of St. Louis, read a paper entitled

A PLEA FOR MORE DETAIL IN THE TREATMENT OF RAILWAY INJURIES.

Dr. T. E. Russell, of Springfield, O., read a paper on

RAILWAY SURGERY,

in which he leaned toward primary amputation. He said in severe injuries to the arm, near the shoulder, requiring amputation, it often happens that the lesion is so near the articulation that it is next to impossible to secure a good flap by any methods laid down in text-books. A convenient and proper way, if the sound tissues favored the scheme, is to make the first incision in the course of the humerus, splitting the deltoid muscle and going directly to the shoulder-joint. A strong bistoury is introduced below and a little in front of the acromion process, and a longitudinal cut is made in the course of the limb to a point an inch and a half below the surgical neck of the humerus. At the middle of this incision the scalpel is placed in the wound, and carried obliquely downward in front and behind, making two lateral flaps, as it were. These lateral cuts should not be deep enough in front or toward the axilla to sever the arteries, but to make space for disarticulating the head of the humerus from the glenoid cavity. The remainder of the amputation is completed by returning to the lateral or oblique incisions—to the posterior first—and cutting each away till the arm is severed. The flaps adjust nicely, and the results are all that can be desired, if the healing processes meet with no mishaps.

Photographs were passed around of the cases on which Dr. Russell had operated.

Dr. H. H. Middlecamp, of Warrenton, Mo., advocated primary amputation where there was no possible chance of saving the limb. Injuries produced by railway cars were more profound and severe than those received otherwise, owing to the relative speed, the weight of the cars, etc. There is very little difference, however, between some railway injuries and those sustained in large manufacturing establishments where there is powerful machinery. The surgeon should exercise his judgment as to whether amputation should be performed immediately or delayed.

Dr. Alex. W. Atchison, of Denison, Tex., said it was surprising to find what little support the surgeon had in regard to primary amputation. He had searched the different authorities on this subject. Personally he would favor immediate operation.

Dr. R. Harvey Reed, of Mansfield, O., was in favor of the primary operation. When the surgeon waits for shock in severe railway injuries, or in a case where heavy machinery has gone over a limb, he only waits for the undertaker, for almost invariably the patient dies.

Dr. J. H. Bennett, of Wauseon, O., advocated primary amputation. One of the principal elements of reaction and repair is rest. The surgeon should, therefore, put the patient at rest as soon as possible after the injury. This could not be done, however, in the case of a badly mutilated limb, and, the surgeon should perform amputation before reaction sets in.

Dr. J. H. Murphy, of St. Paul, had been a railroad surgeon for twenty-four years. The time to operate depended wholly and solely on the judgment of the surgeon. A man without judgment was not fit to be a railroad surgeon. He did not think there was any surgeon who could go into court and testify when an amputation should be done.

Dr. W. L. Schenck, of Osage City, Kan., protested against one thought brought out in the paper, that the operation should be performed immediately. It was misleading to the young surgeon.

Dr. Mansfield, of Nebraska, called attention to the nervous system and brain as a distinction between railway and military surgery. The surgeon has no more joyous, hopeful subject to contend with than the boy who works on a railroad; whereas in military surgery the excitement during engagements is such that any injury is accompanied by a severe shock that will kill the patient. Where a patient had sufficient vitality to withstand an operation, he would not hesitate to perform it.

Dr. Allen, of Liberty, Mo., said gunshot wounds were rarely followed by much hemorrhage. He had never seen a severe hemorrhage during the whole war; whereas in railway injuries one of the prominent features is hemorrhage. This he thought was a sufficiently striking distinction between railway and military surgery.

With regard to operating, he presumed no surgeon would operate on a pulseless patient, or one in whom collapse would develop following shock. When, however, the indications were such as to justify an operation, he would certainly do it.

Shock, he thought, could be overcome by alcoholic stimulants, coupled with large doses of morphine, one-half of a grain of the latter, if necessary, followed by the use of chloroform. He believed that ninety-five per cent. of all the cases of shock could be thus overcome. If the pulse rallies under chloroform, he regards it as a sign of success.

Dr. S. S. Thorn, of Toledo, O., would operate if the patient rallied under an anæsthetic. He then referred to the septic period. Somebody wrote: "Woe to the surgeon who operates in this period." According to his observations, patients operated upon during the septic period, as a rule, died.

Dr. Outten said there was one element that had borne him down and which he had been thoroughly incompetent to treat, and that was shock. He would venture to say, in violent railway injuries, that thirty-three and a third per cent. of the cases die of shock before the surgeon can interfere.

Dr. C. B. Miller, of Lawrenceburg, Ind., said in railway injuries and accidents the shock is greater, for the reason that in a large number of cases those who are injured on railways see the object that is coming; while those who are wounded in the army, are wounded without knowing they have been struck until a short time after.

He could not agree with Dr. Allen, who had said that gunshot wounds rarely gave rise to much hemorrhage. He had made a great mistake, for they were much more liable to bleed than some of the injuries received on railroads.

Evening Session.

Dr. Reed read a communication from the Secretary of the American Public Health Association, the latter requesting the former to appoint some member to prepare a paper on Railway Sanitation, to be read at the next annual meeting of the Association, to be held in Brooklyn, N. Y., October 23d, 24th, and 25th.

No action was taken on the communication.

Dr. Robert Barclay, of St. Louis, read a paper entitled

THE WHISTLE SIGNAL,

in which he recommended aural tests to be scientifically applied to all railroad employees just as color tests are now applied.

Dr. Murdock thought the suggestions offered by the essayist were good. The engineer should have a good ear as well as a good eye, and considerable attention had been given to the latter of late in the employment of engineers, firemen, and pilots on vessels. The matter of the ear should engage the future attention of railway surgeons, and he would suggest that they be included under one head, if it is thought well to act on the suggestions of the essayist, as ophthalmology and otology usually go together.

Dr. Adolph Alt, of St. Louis, read a paper entitled

PTERYGIUM AMONG RAILROAD MEN,

which was referred to the Committee on Publication.

Recording Secretary Stemen made a stirring appeal for the spread of the sentiments which gave rise to the formation of the Association.

The Corresponding Secretary read a few of the many letters he had received from the general managers of railroads pertaining to the organization, the tenor of which was very flattering to the Association.

Second Day, May 3d—Morning Session.

Dr. Alexander W. Atchison, of Denison, Tex., read a paper on

RAILROAD STRETCHERS.

The paper was discussed by Drs. Mansfield, Outten, and A. W. Ridenou, of Massillon, O.

A further discussion on the establishment of union hospitals followed at this juncture, which was participated in by President Jackson, Dr. W. P. King, of Kansas City, and Dr. Ridenour.

Dr. Fulton, of St. Paul, read a paper on

RAILROAD INJURIES OF THE EYE.

Afternoon Session.

Dr. Reed contributed a paper entitled

CLINICAL OBSERVATIONS ON SOME OF THE EFFECTS OF DIRECT AND INDIRECT TRAUMATISMS OF THE BRAIN.

The paper passed without discussion.

OFFICERS FOR 1890.

President, Dr. J. B. Murdock, Pittsburg, Pa.; *First Vice-President*, Dr. W. B. Outten, St. Louis, Mo.; *Second Vice-President*, Dr. Elliott, Atlanta, Ga.; *Third Vice-President*, Dr. W. B. Rogers, Memphis, Tenn.; *Fourth Vice-President*, Dr. J. F. Pritchard, Manitowoc, Wis.; *Fifth Vice-President*, Dr. G. P. Conn, Concord, N. H.; *Sixth Vice-President*, Dr. T. P. Livingston, Plattsmouth, Neb.; *Seventh Vice-President*, Dr. F. J. Bancroft, Denver, Col.; *Recording Secretary*, Dr. C. B. Stemen, Fort Wayne, Ind.; *Assistant Secretary*, A. G. Gumaer, Buffalo, N. Y.; *Corresponding Secretary*, Dr. E. R. Lewis, Kansas City, Mo.; *Treasurer*, R. Harvey Reed, Mansfield, O.

The Association then adjourned to meet in Kansas City the first Thursday in May, 1890.

The Propeller Bone.—Dr. C. M. Dodson, writing in Leonard's *Illustrated Medical Journal*, says that the innominate bone is a facsimile of a marine screw propeller, and that he has used it in propelling a pleasure boat, fifteen feet in length, finding that the boat could be driven by it very satisfactorily. He thinks, therefore, that it may at last receive a name, and finds none more appropriate than that given above.

INDIANA STATE MEDICAL SOCIETY.

Fortieth Annual Session, held at Indianapolis, Ind., May 1 and 2, 1889.

The President (Dr. W. H. Wishard) called the Society to order.

THE SECRETARY'S REPORT

showed a gain of six county societies and seventy members over last year. The mortality list was not a lengthy one, but included two ex-presidents—Drs. W. H. Field and Benjamin Newland—also Dr. Moses Baker, of Stockwell, the first surgeon in Indiana to perform ovariotomy, and Dr. Mary Thomas, of Richmond, the first female doctor to become a member of the Society. About eighty out of the one hundred counties in the State have county societies, and all members of the State Society. A man cannot be a member of the State Society unless a member of the County Society, and being a member of the latter makes him a member of the former. The fees are paid to the County Society, and the names and fees turned into the State Society. For one dollar a man becomes a member and receives the "Transactions." The Society is the largest and most thoroughly organized State medical society connected with the American Medical Association. It can be safely said that in the near future public opinion will compel every physician to unite himself with the State Medical Society, thus to sustain the honor and dignity of the profession, and rebuke charlatanism and obtrusive effrontery under whatever guise they may appear. The whole number of members is now twelve hundred. The Treasurer's report showed the financial affairs of the Society in a prosperous condition.

Dr. Lomax, of Grant County, at the meeting of last year, proposed a plan

FOR THE IMPROVEMENT OF THE INDIANA MEDICAL COLLEGE.

It was for the county medical societies to secure the pauper practice in the counties, and donate the fees paid to the college. The duties of the pauper practice could be done by the members in turn, and would not be hard on any one. The committee reported adversely to this proposition, for the reasons that the State Society could not well manage a large, well-endowed college, as a vast amount of competition and rivalry would arise among the applicants for faculty and managing positions, and everything would be in confusion. Then, the county societies could not get the pauper practice in all cases, if they tried. There were so many irregular physicians, and so many regular ones who do not belong to the county societies that they would underbid. The committee also reported that in Indiana there are 3,243 regulars, or allopaths; 287 eclectics; 199 homœopaths; 142 physio-medicals; and 192 unclassified. Less than one-third of the regulars are not connected with the county societies.

THE COMMITTEE ON ETHICS

had some delicate matter to attend to, which was handled with all due care and tact. A committee appointed for that purpose endorsed the National Formulary.

Dr. Kate Corey, a graduate of Michigan University, and Superintendent of the Methodist Hospital at Foochow, China, was introduced to the Society, and made a brief speech. Her great work was related by the Secretary, and a motion to make her an honorary member was passed without a dissenting voice.

The Committee on Ethics asked the appointment of a committee to draw up some uniform rules by which a member shall be tried by the county societies. The request was granted.

Dr. E. S. McKee, of Cincinnati, was introduced as delegate from the Ohio State Society, and delivered a message of good-will and greeting.

OFFICERS ELECTED.

President, Dr. J. D. Gatch, Lawrenceburg; *Vice-President*, Dr. S. Y. Yonte, of Lafayette; *Secretary*, Dr. E. S. Elder, Indianapolis; *Assistant-Secretary*, Dr. T. C. Kennedy, of Shelbyville; *Treasurer*, Dr. F. C. Fergueson, Indianapolis.

THE PRESIDENT'S ADDRESS

was a retrospect of the practice of medicine for the past half-century. He considered this period one of great progress in science as well as other things. The great thing is, have we as medical men kept abreast with the times? He endeavored to make his answer convincingly in the affirmative. The primitive Indiana doctors had not great advantages of education. In 1817 the Transylvania University at Lexington, Ky., opened a Medical Department, and in 1818 John L. McCulloch was the first graduate in medicine west of the Alleghanies. This soon grew to the second medical school of the United States. In 1819 the Medical College of Ohio, at Cincinnati, and in 1837 the Medical Department of the University of Louisville were formed. Not ten per cent. of the physicians of Indiana in 1825 were graduates, and only twenty to twenty-five had taken one course in medicine.

EPHRAIM McDOWELL WAS NOT A GRADUATE,

but after thirty years of practice the University of Maryland gave him the degree of doctor of medicine honorary. There was but one medical journal in the United States in the early part of this century, the *Medical Repository*, of Philadelphia. Obstetric business was all in the hands of females. It was necessary. Physicians were scarce, women were healthy, and nature needed but little aid. Such an affair was quite a celebration to the female portion. Not to be invited was a great slight. The physicians were looked upon with suspicion in this line of practice, and were not summoned unless there was great necessity. When summoned the news spread like wildfire, and the neighborhood turned out *en masse*, as though it was a funeral or a wedding. A log cabin twelve by fourteen feet would be literally packed by women and children, with sometimes a few men. Early settlers were almost exempt from tuberculosis, diphtheria, and cerebro-spinal meningitis. Only the strong and healthy ventured to the front. In winter pleurisy and pneumonia raged. The doctor was a dealer in second-hand goods. Four-fifths of the fatal cases had been treated by the old women till the case was hopeless. He well remembers when quinine first came into use. He was given a prescription consisting of thirty grains of quinine, ten drops of dil. sulphuric acid, and six ounces of water; dose, teaspoonful, to be taken three times a day with great care. He has known

AN OLD THUMB LANCET

to descend as an heir-loom from the father to son and grandson, and had drawn more blood than some regiments in the late war. An old theory was that if you would draw blood from the right arm when the pain was in the left, you would draw the pain across the heart and kill your patient. The curtain was first lifted in the treatment of fevers by Dr. Lunsford P. Yandell, of Louisville, and the light has been shining more and more ever since. He thought the domain of surgery had made wonderful progress in the last fifty years. The good dame of fifty years ago would show her ten or a dozen sons and daughters, the pride of her life, the hope of her future. To-day we are shown one son or daughter and a poodle dog—often only the poodle dog—all the hope of this family. The doctor then paid some

SCATHING TRIBUTES

to criminal abortion, and went on to discuss the fortieth anniversary of the Indiana State Medical Society. Organized June 6, 1849, twenty-eight physicians were present, of whom now only five are living, four in Indiana and one in Texas.

Dr. King, of Indianapolis, related the incident of his father and mother both dying within seven minutes of each other, from being bled, forty years ago, only a few miles from Indianapolis.

Dr. Leech, of Indianapolis, spoke on criminal abortion, and told an interesting story of how he saved two twin girl babies, and what pleasure he derived by seeing them playing on the hillside as he drove past their home.

Dr. G. W. H. Kemper, of Muncie, Ind., read a paper entitled

ANTISEPTICS IN NORMAL LABOR

The doctor had attended nine hundred cases of labor in civil practice, and in no one instance had he used a single antiseptic measure before or after parturition. Two of these women died, one of puerperal convulsions and the other of acute pneumonia. He had no case of severe puerperal fever among his nine hundred cases. The cases were of the average gravity, as proven by the particulars which were given. He had some cases which would have demanded the antiseptic treatment if any did. They did not get it, and recovered all the same. If he had used this treatment what encomiums he could have bestowed upon the practice! A class of recent converts to antiseptics charge that all who do not avail themselves of this practice are criminally negligent. The health officer's reports in Delaware County—the county in which the writer resides—gives a ratio of 7.5 deaths per 1,000. This included the practice of doctors, midwives, and old women; 10 out of 34 deaths were due to accidents which could not be affected by antiseptics, which presents a more favorable outlook than the hospital practice of the larger cities with antiseptic precautions. He considered the paraphernalia and details of antiseptic midwifery, as laid down by Thomas, Garrigues, and others, to be both expensive and tiresome. He had, without the formality of an introduction, witnessed a number of deliveries within five minutes from his entry into the house. In such cases the time for the antepreparatory antiseptic treatment of Professor Thomas would not equal in opportunity that of a death-bed repentance of a subject of Judge Lynch. While he would do something toward antiseptics where it seemed necessary, yet he would not feel it advisable in every case of normal labor, when a patient is surrounded by healthy environments, to attempt to carry out a complicated routine of practice which his experience teaches him is uncalled for.

The doctor, in conclusion, submitted the following aphorisms:

1. The history of obstetrical practice teaches us that the lying-in hospital has always been a place of danger and mortality, therefore it is obligatory on those who have charge of those institutions to utilize every antiseptic measure known to the profession to save life.

2. The experience of country practitioners teaches us that women who are confined in healthy isolated rural homes are not subjected to the contaminating influences of an ochlesis, and consequently do not require all the precautions of those exposed to hospitals, or even to the atmosphere of city life.

3. That the country practitioners of medicine will generally show a lower rate of mortality in obstetrical cases than city practitioners, simply for the reason that they practise in healthier localities and less exposed to contagious influences, and possibly have a healthier class of patients.

4. That the insinuations of a number of late writers on antiseptic midwifery, that the death-rate in obstetrical practice of country practitioners is high, are not true, as shown by statistics.

The drift of the discussion was not in accord with the views expressed in the paper.

Dr. James F. Hibberd, of Richmond, Ind., read

AN INTERESTING PAPER ON MYXŒDEMA,

with report of case. His patient was a lady, aged fifty,

previously slight in build, but although her general health had been failing during several months her weight was one hundred and forty-three pounds when she consulted him. She suffered from a sense of general weariness, abatement of mobility, disinclination to active exercise, and lessened ability to concentrate her mind on any important affair. Her skin had become dry, pale, and sallow, and was swollen and puffy, particularly about the feet and hands, but gave her most discomfort from the thickness and weight of her eyelids and surrounding tissues. Her limbs had lost their normal suppleness, and she walked with an unsteady gait; her hands were stiff and swollen, making it almost impossible to hold a pen or write. She complained of general subjective cold, and her temperature was found subnormal. She presented a depreciation of vital activity and a sluggishness of mental operations. Examination displayed no special error in respiratory, circulatory, urinary, or uterine functions.

The patient was advised to cease her literary occupations; moderate outdoor exercise, with quinia, strychnia, and iron soon brought a slow improvement in her condition, though she still presents a remnant of her serious ailments of two years ago. This is a typical case of myxœdema, a mild attack of favorable progress and promising prognosis, but presenting all the characteristic symptoms of the disease.

THE FIRST DESCRIPTION OF MYXŒDEMA

was by Gull in 1874, and in 1876 Ord gave a thorough exposition of its leading characteristics and proposed the name, as he declared mucin was found in the tissues of all its victims. Hammond gave a short description of the disease in 1881, and the treatises on general practice since have had chapters devoted to myxœdema.

The *American Journal of the Medical Sciences* published two papers, in July and August of 1888, by Drs. Hun and Budden, giving thorough details of four cases under their observation, and of the literature of the subject. Excluding cases due to the extirpation of the thyroid gland for disease, and those associated with idiocy and cretinism, there are one hundred and fifty-four cases of idiopathic myxœdema more or less completely reported, according to their researches. The conclusions reached by them are: There are more than three times as many females affected as males; the average age for the beginning of the disease is forty years; chief etiological factors are excessive child-bearing, excessive hemorrhage, mental shock and worry, and injuries, especially of the head. Myxœdema appears to manifest itself by very characteristic symptoms, which affect especially the cutaneous, nervous, and vascular systems. Cutaneous: Skin swollen without pitting, dry, scaly, and cold; hair and teeth frequently fall out. The mucous membranes are swollen but their secretion is increased, while perspiration is absent or greatly diminished. Nervous system: Mental sluggishness and impairment; insanity frequent; impairment of sensibility in most cases; in all cases muscles act feebly; numbness and neuralgic pains are often present. Muscular system: Pulse usually slow and small, and heart presents some abnormality. Blood often in an anæmic condition, sometimes severe hemorrhages. A clear, succinct, comprehensive statement of our present knowledge of this disease is found in the summary of Dr. Ord, printed in the London *Lancet*, June 2, 1888, and copied in the *Medical News*, Philadelphia, June 23d.

The author concludes with the statements that he thinks myxœdema a distinct disease with well-marked symptoms; its diagnosis is easy and certain; it is not amenable to treatment, and persons affected with the disease never regain a perfectly normal condition. He thinks it quite possible to meet associated disturbances with remedies, and by proper use of exercise and rest to carry persons through years of comparative ease.

Dr. W. N. Wishard, of Indianapolis, read a paper entitled

URETHRAL STRICTURE IN THE MALE.

He followed Otis' classification and location of stricture. He discussed the subject of electrolysis in stricture, but was unsatisfied in his own mind as to its utility. At present he finds no method so successful as Otis' operation. It is the only method in which he feels confident of curing the stricture. Absence of fatal, or even serious results, have led him to consider it a safe method, though he avoided operating in cases of kidney trouble.

Dr. A. G. Porter, of Lebanon, Vice-President of the Society, read a paper entitled

NERVOUS SICK-HEADACHE.

Concerning this disease, he said, little was written and little known; the treatment was unsatisfactory, and the disease very frequent. He thought ninety-nine per cent. of cases are due to a deficient supply of blood to the brain or some part of it. An ounce of sherry wine or brandy, in a glass of soda-water, was good in many cases where there was a chill and depression present, but in many others was unadvisable. Valerian and assafœtida are very good, two or three drops of dilute hydrocyanic acid and an emetic, if the stomach is at fault. We must abridge hours of study or work.

Dr. Howes, of Richmond, has cured several cases, when due to stomach trouble, by bismuth and fluid extract of quassia.

CHOLETHOTOMY

was the subject of a paper by Dr. Miles F. Porter, of Fort Wayne. He favored the continuous suture after Tait's method.

"A Case of Suppurative Peritonitis" was the subject of a paper by Dr. G. W. McCasky, of Fort Wayne, and "Glaucoma" by Dr. A. Blitz, of Indianapolis.

THE NATURE AND ETIOLOGY OF TUBERCULOSIS

was the subject of a paper by Dr. R. F. Stone, of Indianapolis. He did not believe in the theory of contagion, and opposed bacteriology and all the ideas of Koch.

Dr. A. W. Brayton, of Indianapolis, admired the doctor's courage to write such a paper as this at this time; for it took courage to make such antiquated statements.

Dr. Theodore Potter, of Indianapolis, considered tuberculosis inoculable, and the only cause the tubercle bacillus of Koch. Where the tubercle exists the bacillus exists, and we have in the tubercle bacillus a positive diagnosis of tuberculosis. If the tubercle bacillus is excluded by a careful examination, we can exclude tuberculosis. Not to believe in the tubercle bacillus we might as well not believe in the spermatozoids which made us.

Dr. Stone, in reply, wished to be put on record that he was opposed to this fallacious theory of germs. "It is a myth. I do not believe in antiseptics only so far as it induces cleanliness."

BRONCHO-PNEUMONIA IN CHILDREN

was the subject of a paper by Dr. G. W. Vernon, of Indianapolis. He used this term purposely because he meant it, and thought it the proper term. He thought the burning of natural gas in this city had become a great factor. The houses had been kept too warm, and dry-mouth breathing was also coming to be a prominent cause. He thought the disease occurred more frequently among children than adults. The disease may commence in the tubes and extend into the alveola and *vice versa*, or may commence in the interstitial tissue. In treating the measles, whooping-cough, etc., we should keep under consideration the possibility of this disease.

Dr. Johnson, of Indianapolis, was pleased that the doctor insisted on the term broncho-pneumonia. He thought there were more recoveries from acute lobar pneumonia than from broncho-pneumonia, as the latter is apt to be neglected by the patient.

Dr. G. V. Woolen would only criticise the doctor in one point, and that is, that he scarcely went above the epiglottis or larynx in his genesis of the trouble. He thought the whole life of the respiratory organs was to be found in the head at the base of the brain. Catarrhal disease he thought essentially a disease of childhood; no man in this body who has not catarrh already will ever, in his opinion, acquire it.

THE HYDRO-THERAPEUTIC TREATMENT OF TYPHOID FEVER

was the subject of a paper by Dr. G. W. Smythe, of Greencastle, which was followed by a paper on

ATYPICAL TYPHOID FEVER,

by Dr. H. McCullough, of Fort Wayne. He thought irregular typhoid fever much more frequent than generally supposed.

Dr. M. F. Porter thought there were more cases of the atypical typhoid fever than the typical. Authors of text-books, he thought, had made a great mistake. He opposed the general routine treatment of typhoid fever by cold baths, yet he thinks cold baths in a great many cases are beneficial.

Dr. Leech thought the great question was, Are you capable of diagnosing a case of typhoid fever?

Dr. Lomax, of Grant County, had been studying typhoid fever for a long time, but could not now give a good definition of it. It had been thought that the disease should be given a name having some connection with the spleen. He considered the classification of Trousseau into adynamic, ataxic, and typhoid fevers the best.

Dr. Mendenhall, of Richmond, said there were 300,000 cases of typhoid fever in the United States each year, and 30,000 of these die. We ought to be interested in this disease. We can never know exactly how to treat it until the disease is understood, and he believed we do now understand it. He believed it was caused by germs. When we can kill or stop the production of these germs the cause will be gone and the disease will stop. If we give quinine we will get trembling, nervous conditions, and hallucinations. If we leave off this and tonics we will not have so much of this kind of trouble. Early in the disease he gives small doses of calomel or bichloride and turpentine, oft repeated—two drachms to one pint of turpentine emulsion and two grains of calomel. He does not use antipyretics.

The discussion on this disease grew quite lengthy, and a gentleman rose to a point of order, saying we were already far behind the programme.

The President replied that he knew it, and we were leaving typhoid fever about where we found it.

Dr. Smythe, in replying, said the whole question was simply one of diagnosis. Will we permit our patients to die of secondary troubles or not? He uses Von Ziemssen's graduated bath and gives quinine in forty-grain doses, having given as high as seventy grains.

TENNESSEE STATE MEDICAL SOCIETY.

The Tennessee State Medical Society met in its regular annual session at Nashville, April 30th, May 1st, and 2d, with the President, Dr. T. J. Happle, of Trenton, in the chair, and the Secretary, Dr. D. E. Nelson, of Chattanooga, at the desk. The Treasurer reported $169.68 in the treasury. Much attention was paid to legislation, and it was reported to the Society that, as the results of forty years' labor, the Legislature had at last been persuaded to pass a law regulating the practice of medicine. Though this was far from perfect, yet it was a great gain, and all should give it their hearty support.

The following gentlemen were recommended to the Governor for appointment as a Board of Examiners: Drs. S. C. Deadrick, Knoxville; J. B. Murfee, Murfreesboro; D. D. Saunders, Memphis.

A resolution requesting the Legislature to pass the bill now pending, requiring the registration of births and marriages, was passed.

Election of officers resulted as follows: Dr. Duncan Eve, Nashville, *President;* Drs. Henry Berlin, Chattanooga; James B. Neil, Marshall, and J. P. C. Walker, of Dyersburg, *Vice-Presidents;* Dr. E. D. Nelson, of Chattanooga, *Secretary*, and Richard Cheatham, of Nashville, *Treasurer.*

The next meeting will be held at Memphis, the second Tuesday in April, 1890.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, May 3, 1889.

Francis P. Kinnicutt, M.D., President, in the Chair.

Dr. Samuel Sexton read the paper of the evening (see p. 589), entitled

THE CARE OF THE TEETH, FROM A MEDICAL PRACTITIONER'S STAND-POINT.

Dr. A. H. Smith thought the instruments shown by the speaker might be very useful in removing the little flaps of gum, a manœuvre which he had sometimes been rather embarrassed in executing with the instruments at his command.

Dr. Beverley Robinson said that earache, or even a discharge from the nose, was not infrequently due to some trouble with the teeth, but it was more common to find neuroses in the pharyngeal region from this cause. He believed that amalgam fillings were especially injurious, and it was his custom in cases of this kind, when the ordinary remedies failed, to send his patient to the dentist in order to have any amalgam fillings that might be present removed. He saw a patient recently who had been under his care some time ago. This man had suffered greatly from pain in the pharynx, especially at night, and no relief had been obtained by any of the remedies employed, such as sprays and local applications, or even from anodynes given in doses as large as was consistent with safety. There was no local trouble apparent. Finally, some amalgam fillings in his teeth were removed, and then his troubles ceased.

Some time ago he had attended a lady suffering from a very severe attack of mumps. After the disease had subsided there was considerable swelling left around the angle of the jaw. A needle introduced into the swelling gave no evidences of the presence of pus. As the swelling persisted, massage was finally employed, and this was followed by a discharge of pus into the mouth. On the second day after the massage was begun the lady complained of a feeling of "goneness" and weakness, and as this seemed to be connected with the massage the latter was stopped. The speaker asked whether massage ought to be used in cases like this, in which there was a suppurating process around a tooth, when medicinal means were of no avail, and surgical measures, for one reason or another, could not be employed. In this case the massage treatment certainly had a beneficial effect as far as the pain was concerned, but was it harmful in causing the absorption of the pus?

Dr. C. L. Dana said that he had never seen any nervous disturbances which could be attributed directly to the process of second dentition. Nearly all the neuroses of childhood, such as headache and the like, develop a little later than the period of dentition. He could not now recall many cases of reflex troubles from bad teeth. He had seen a few cases of brow neuralgia, accompanied by a dilated pupil and slight suffusion of the eye, which were apparently due to this cause. There was an old medical superstition which ought to be done away with, and that was that tic-douloureux was caused by bad teeth. He had had patients with this trouble who came

to him with nearly all their teeth pulled out, yet their pains continued as severe as before.

In hereditary ataxia there is sometimes seen a condition of the teeth resembling very closely that described by Hutchinson as characteristic of hereditary syphilis.

Dr. Joseph D. Bryant said that he saw no need of a special instrument for the removal of the gum flaps referred to by the reader of the paper. He had always found that scissors curved on the flat answered the purpose very well.

Dr. Clement Cleveland referred to a case of severe supraorbital neuralgia coming on every afternoon, in which the pain was so intense that the sufferer was compelled to go to bed. Many remedies were tried without avail, and finally a dentist was consulted. He first removed the filling from one of the wisdom teeth, and then, no relief following, extracted the tooth. There was found to be commencing degeneration of the nerve, but the loss of the tooth caused no diminution of the pain. A cure was finally effected by means of quinine.

Dr. V. P. Gibney said that he had found peg-teeth very commonly in hospital children suffering from joint lesions. Formerly these teeth were called scrofulous or strumous, but now they would probably be called tuberculous teeth. He had seen very few cases in which the teeth were like those described by Hutchinson as the teeth of hereditary syphilis.

Dr. Sexton, referring to the case mentioned by Dr. Robinson, said that one of two things would have probably been found to exist: either the tooth had suppurated at the root, in which case pressure from pus or gases might have caused the trouble; or if the tooth possessed its pulp, it might be that the amalgam filling was so near that it would transmit the heat or cold. He did not mean to convey the idea that deafness was caused directly by the presence of the diseased tooth, but desired simply to refer to the conditions in which deafness might be produced by reflex causes. He referred to a case which he had seen some time ago, of a patient who had pains in the ear, chest, and various other places. He could find no trouble in the ear, and Dr. Robinson, to whom he referred the patient, could find nothing wrong in the chest. Examination of the mouth showed the presence of a carious tooth; this was extracted, but no relief followed. On more careful examination, however, an old root was found in the jaw, and when this was removed the patient recovered entirely. In the case of so-called dead teeth, as long as they remain unfilled the pus and gas will escape, but when such a tooth is filled there is no chance for the escape of the pus and gas. Filling a dead tooth is, therefore, bad surgical practice. He did not agree with Dr. Dana, that tic-douloureux is never caused by the presence of bad teeth in the mouth. It might well be that no relief would follow the removal of the offending teeth, but this would not prove that they were not originally the cause of the trouble.

Dr. F. P. Kinnicutt and Dr. Wm. T. Bull then presented a report of a case of

PYLORIC STENOSIS RELIEVED BY LORETTA'S OPERATION.

(This paper will appear in a future issue.)

Dr. George L. Peabody said that a correct diagnosis in cases of this nature was extremely difficult to make. A diagnosis of pyloric stenosis might be made without much difficulty, but the trouble was to determine the nature of the stenosis, and whether it was such as would admit of stretching. For instance, there might be a localized peritonitis which had caused adhesions to a neighboring viscus, thereby occluding a perforation from an ulcer, and any disturbance of these adhesions would unseal this opening.

Dr. Kinnicutt said that the surgeon should always be prepared to abandon the operation if the conditions were found to be unsuitable, or to perform some other operation such as resection. It was, of course, impossible to make a full diagnosis of the exact condition present in such cases.

Dr. Bull said that the presence of adhesions had been considered a contraindication to this operation. It might be possible, however, in certain cases, to perform an enterostomy.

Dr. Kinnicutt said that this was the sixth case of pyloric stenosis that he had seen in the past two years. In four of these cases a small tumor could be detected on palpation. In those cases in which the tumor was easily movable no adhesions were found at the time of operation, but in those in which it was fixed, adhesions were found to be present. Whether this would prove to be a point of value in the diagnosis he could not say at the present time, but it seemed as though it might possibly be of some practical use in forming an opinion as to the probable success of an operation.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

SUCCESSFUL TREPHINING FOR CEREBRAL HEMORRHAGE—A CASE OF TRAUMATIC EPILEPSY—EXOPHTHALMOS CAUSED BY INTRANASAL OPERATIONS WITH THE GALVANO-CAUTERY—A CASE OF XANTHELASMA WITH MULTIPLE TENDON ENLARGEMENT—CAN FIBRES IN THE SPINAL CORD BE REGENERATED?—THE PRESIDENCY OF THE ROYAL COLLEGE OF PHYSICIANS—A REMARKABLE CASE OF TOTAL EXTIRPATION OF THE LARYNX WITH PARTIAL PRESERVATION OF THE VOICE—OUT-PATIENT WORK—A NOVEL DEPARTURE IN MEDICAL LITERATURE—THE REGISTRATION OF DEATHS—A NEW SCHEME OF NAVAL MEDICAL SERVICE—DR. CLIFFORD ALLBUTT.

London, April 22, 1889.

At the Clinical Society's last meeting several communications of interest were brought forward. Mr. Herbert Allingham related a case in which he trephined with success a patient who was the subject of head injury. A large blood-clot was found, not between the dura mater and the bone, but between the dura mater and the pia mater. The case was therefore one of cerebral hemorrhage, and as such Mr. Allingham said he believed it to be unique. The next paper was by Dr. Lees and Mr. Page, and gave an account of a case of epilepsy following injury, in which trephining was performed without success. The aura always began in the left foot. On percussing the skull, a tender spot was found situated in the posterior superior region of the right half of the skull, quite close to the median line. It was about an inch and a half in diameter, and its centre was about three-fourths of an inch behind the upper extremity of the fissure of Rolando. The patient was trephined over the tender area, and a disc of bone removed as near the median line as was thought safe. The symptoms were only temporarily relieved, and on the fifteenth day after the operation a violent fit occurred. Two hours later another followed, and it was so violent that chloroform was administered. The patient died under anæsthesia. At the post-mortem the pia arachnoid was found markedly milky in appearance over the whole convexity, and there was a considerable excess of subarachnoid fluid. There was hyperæmia and some softening of both gray and white matter at the site of the wound (which was perfectly healed). The inner surface of the skull-cap was found to be roughened behind the vertex, along the line of the longitudinal sinus. A small osteophyte was found situated three inches behind the coronal suture, and in the left line of attachment of the longitudinal sinus. It was one-tenth of an inch in length and the same in breadth, but was raised only about one-sixteenth of an inch above the level of the surrounding bone. The authors exhibited the skull-cap, and desired to obtain the judgment of the Society as to whether an osteophyte so small and in such a position could have been the cause of the symptoms? As to this, however, no decided answer was given by any of the speakers in the

ensuing discussion. Dr. Lees, in his reply, agreed with some of the speakers that attacks of "Jacksonian epilepsy" might arise from functional or nutritive lesions. The point, however, was that in this case the attacks were accompanied by an area of tenderness over the cortical centre, the nutritive or other irritation of which might be supposed to give rise to the fits. Either there must be some coarse lesion causing the fits, or we must give up the view that the presence of the zone of tenderness was to be taken as an indication of a brain lesion.

Dr. Semon then brought forward a case (patient shown) in which intranasal operations with the galvano-cautery for the removal of multiple recurrent mucous polypi had been succeeded by some symptoms of Graves' disease, viz., exophthalmos of the right eye, accompanied by Graefe's symptom (lagging behind of the upper eyelid when the patient looked down) and Stellwag's symptom (retraction of the upper eyelid). The symptoms came on within a day or two after the operations. Dr. Semon referred to some cases on record in which intranasal operations had been followed by the diminution or disappearance of symptoms of Graves' disease, but his case was an example of the hitherto (he believed) undescribed possibility of causing unfavorable changes in the domain of the sympathetic. A remarkable fact in connection with the case was that the intranasal operations had cured the patient of one neurotic symptom, asthma, from which he had begun to suffer soon after the appearance of the nasal polypi. Mr. Brudenell Carter said he was almost disposed to look upon the alleged connection between nasal operation and exophthalmos as a mere coincidence. He was convinced that in Dr. Semon's patient there was in reality little or no protrusion of the eyeball, and he suggested an operation by which the deformity could be remedied. Dr. De Haviland Hall suggested that the removal of the polypi should be proceeded with, in the hope that the opposite effect might now be produced. Operations on the nasal cavities seemed able to cause two sets of effects. Mr. Hutchinson then related a case of xanthelasma in a gouty patient, accompanied by multiple tendon enlargement.

In Dr. Tooth's recent Gulstonian Lectures ("On Secondary Degenerations of the Spinal Cord") at the Royal College of Physicians, he alluded to the controversies as to the possibility of the regeneration of fibres in the spinal cord. Experiments on the lower animals, he said, pointed to the possibility of some amount of repair in them, and also to its greater activity in young animals. In man, however, there was little evidence of this power. In a case under the care of Dr. Gowers and Mr. Horsley, however, complete recovery ensued on the removal of a tumor which, by indenting and pressing on the cord, had induced paralysis with increased reflexes in the lower limbs.

Sir Andrew Clark has been re-elected President of the Royal College of Physicians, receiving 112 out of 116 votes. Though the office is an annual one, the holder is usually re-elected for several years. Five years is the usual tenure of the post, but the late president (Sir William Jenner) was in office for seven years.

London, May 6, 1889.

A very unique case of total extirpation of the larynx was brought before the Clinical Society at its last meeting, in a joint communication from Dr. Greville Macdonald and Mr. Charters Symonds. The patient was a commercial traveller, aged forty-one, who was first seen in April, 1888, when laryngoscopic examination revealed a large, irregularly lobulated growth, occupying the anterior three-fourths of the rima glottidis. It was found by probing to be extensively attached to the infraglottic portion of the right cord. A small superficial ulceration was present on the posterior surface of the growth. A small portion of the tumor was removed for examination, and it seemed to be an epithelioma. Extirpation of one-half of the larynx was urged on the patient, but declined by him. Dr. Macdonald therefore removed the growth with the forceps. It was soft and friable, and there was free hemorrhage. On the following day the voice was restored. No trace of growth could be seen on laryngoscopic examination, but the left cord was uniformly thickened, rounded, and deeply congested, its movements, however, being perfect. A week later, a sharply defined silvery tract (two or three lines in diameter) was seen on its upper surface. Probing proved it to be minutely villous. The growth gradually increased, and an operation was again advised, but another opinion, while admitting malignancy, proved adverse to operation. By October 20th rapid increase had occurred and the growth resembled the one first seen in April but was more congested. Again, an external operation was advised, and Mr. Charters Symonds undertook to perform it. The trachea was opened above the isthmus, Hahn's tube inserted, and chloroform administered through the tube. An incision was then made in the median line, from the upper end of the incision already made to the hyoid bone. The thyroid cartilage was fully exposed and divided in the middle line. The crico-thyroid and thyro-hyoid membranes and the crico-thyroid muscles were then divided. The neoplasm was found to involve the whole of the left cord, and the anterior part of the right looked granular and swollen. The mucous membrane and perichondrium were divided close to the upper border of the cartilage and turned off. The superior cornu was divided and left. The inferior cornu was cut off and the mucous membrane then divided below the cords and back to the arytenoid, and, the ala being drawn forward, the attachment of the arytenoid to the cricoid was severed and this cartilage dissected out from the mucous membrane covering it. The anterior two-thirds of the right cord were then removed and the ends stitched forward with cat-gut. One vessel required a cat-gut ligature. Hahn's tube did not completely prevent blood trickling into the trachea, but a sponge passed into the cricoid ring above the tube was effectual. On the day following the operation Hahn's tube was replaced by an ordinary cannula, surrounded by sufficient gauze to plug the trachea. The patient was fed for five days by an œsophageal tube, but on the sixth day he could swallow, and on the seventh he got up. Three weeks after the operation he was quite well, and his voice was clear and good. A recurrence of the growth soon took place, however, and tracheotomy had to be performed in December. Later, the growth was seen budding on the right side, but being purely intralaryngeal, its total extirpation was proposed and carried out on December 22d, seven weeks from the date of the first operation. Hahn's tube was again used, and the median cicatrix opened. The larynx was isolated by dividing the attached muscles. The cricoid was then separated from the trachea and raised from the epiglottis without injury, the connection of the pharynx to the back of the thyroid divided, and the epiglottis cut through in its lower third. The cavity was stuffed as before, and a feeding tube passed by the mouth and retained. In two days the tube was removed and was passed every four hours by the wound. In ten days the patient was up and about, and on January 8, 1889, was able to swallow. By the end of the month the patient was quite well, save for the escape of saliva through the wound above the cannula. No complication of any kind occurred. The patient was shown to the Society, and appeared to be in good health and spirits. There was now no sign of recurrence. He could speak in a low gruff voice. This was managed by passing through the upper wall of the cannula a curved tube which ran up to the base of the epiglottis and admitted the air when he closed the cannula with his finger. The vocal sound was apparently produced by the vibration of two folds of the pharyngeal mucous membrane which ran backward from the epiglottis. The authors thought there was no previous case recorded of a patient able to speak after total extirpation of the larynx.

Out-patient work is not usually regarded as the most promising field for clinical study. I believe that some at least of the junior members of hospital staffs regard it as

so much necessary drudgery which has to be gone through before they can be promoted to take charge of beds. The amount of out-patient duty which has to be performed varies considerably in different cases, promotion being mainly dependent upon the occurrence of vacancies on the senior staff due to deaths and resignations. Nowadays there is at most hospitals a rule limiting the tenure of in-patient appointments to a period of twenty years. Formerly there was no such restriction, and, in consequence, when the seniors refused either to die or to resign, promotion from the junior ranks might be almost indefinitely postponed. The late Mr. Thomas Wormald, for instance, served as assistant-surgeon to St. Bartholomew's Hospital for a period of, if I remember rightly, thirty-four years, and actually became President of the College of Surgeons while thus holding a subordinate appointment. This was, of course, an extreme case. Within recent years, however, Dr. Cheadle worked at St. Mary's Hospital for sixteen years in charge of out-patients before becoming full physician in charge of beds. There are perhaps a few who would regard this as no hardship, and certain it is that there are many who value at their utmost the opportunities for clinical observation and instruction afforded by out-patients. Among these must certainly be numbered Dr. Byrom Bramwell, of Edinburgh. Dr. Bramwell is one of the assistant-physicians to the Edinburg Royal Infirmary, and, as such, one of the medical officers in charge of the medical out-patient department. He is an enthusiastic teacher and has lately conceived a plan for rendering his teaching available in reaching a somewhat larger circle than those who attend his class. For this purpose he has determined to publish, at fortnightly intervals, during the winter and summer sessions, an account of some of the more interesting and instructive cases which come before him in the out-patient rooms. A somewhat novel method is to be adopted. The cases will not be printed in narrative form, but the questions put to the patient, the patient's answers, and Dr. Bramwell's comments will be published *verbatim* from shorthand notes taken at the time. Dr. Bramwell styles his novel literary venture *Studies in Clinical Medicine*, and the first number of it lies before me as I write. It consists of sixteen small quarto pages, and comprises an account of four cases, together with a brief introduction and some remarks on out-patient practice, the mode of conducting it, and its difficulties, advantages, and disadvantages as a field for clinical teaching and original observation. There are three illustrations in black-and-white, and wood-cuts, lithographs, and, if needed, colored drawings, will, it is said, be freely introduced when required. The author states that he has been deeply impressed with the educational advantages which this method of publication affords by reading the published reports of Professor Charcot's polyclinic, and the plan certainly seems to be one admirably calculated to bring vividly before the mind's eye of a distant reader the various details of important cases.

A memorial has recently been forwarded to the Local Government Board by the Manchester and Salford Sanitary Association calling attention to defects in the existing arrangements for securing a due registration of the causes of death. The memorialists ask that a suggestion of the late Dr. William Farr may be carried out, viz., that registration medical officers be specially appointed in each district of the kingdom, whose duty it would be to view the body of every person dying without being attended by a registered medical practitioner, and after due examination and inquiry, either to give a legal certificate, or, if desirable, to withhold such certificate until an inquest should be held, or until the coroner should have declined to hold an inquest.

An entirely new scheme in connection with the naval medical service is about to be brought into operation. Under certain conditions civil practitioners are to be allowed to enter for temporary service in the Medical Department of the Navy. Numerous applications have already been received, and from among the medical officers who thus serve for short periods a Naval Medical Reserve will doubtless ultimately be formed.

Dr. Clifford Allbutt, of Leeds, has accepted a Commissionership in Lunacy. This will involve his retirement from practice.

THE CRIMES OF ALCOHOLISM AND UNCHASTITY.

To the Editor of The Medical Record.

Sir: The number of The Record for April 27th brought more than its usual compendium of valuable and suggestive matter.

The articles upon "Inebriety," "Narcotism," the plea for "Weekly Rest," and the "Prevention of Syphilis" have all a bearing in the right direction.

The crimes of alcoholism, narcotism, nervous and physical overwork, and unchastity in men or women, are far more needless than is generally supposed. False views held and morbid states of thought and feeling cherished are their living germs. In detecting and destroying these insidious sources of moral and physical disorder the trusted, conscientious physician can do more than all the clergy combined. Dr. Gowers' clear statement of the principles so earnestly maintained by the lamented Acton is as noble as needful and true.

I thank you for your added indorsement, not only on my own behalf but for two young men under my care to whom this article may prove of incalculable benefit. With sincere esteem,

Respectfully yours,
C. A. Greene, M.D.

Castile, N. Y.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 19 to May 25, 1889.

Forwood, William H., Major and Surgeon. By direction of the Acting Secretary of War the leave of absence on surgeon's certificate of disability granted in S. O. No. 35, April 8, 1889, Department of Dakota, is extended one month on surgeon's certificate of disability. Par. 13, S. O. 118, A. G. O., Washington, May 22, 1889.

Middleton, Passmore, Major and Surgeon. Will as soon as practicable after his arrival at Fort Trumbull, Conn., proceed to Fort Warren, Mass., and report for temporary duty until the return of the post surgeon from detached service with batteries of the Fourth Artillery, ordered to Atlanta, Ga. He will then return to his proper station (St. Francis Barracks, Fla.). Par. 2, S. O. 113, Headquarters Division of the Atlantic, Governor's Island, New York City, May 18th.

McElderry, Henry, Major and Surgeon. Granted leave of absence for one month, to take effect upon completion of his duties as a member of the Army Medical Examining Board in New York City. Par. 4, S. O. 117, Headquarters Division of the Atlantic, Governor's Island, New York City, May 23, 1889.

Palzki, J. H., Major and Surgeon. Granted leave of absence for twenty-one days. Par. 1, S. O. 44, Headquarters Department of Arizona, Los Angeles, Cal., May 18, 1889.

Appel, Aaron H., Captain and Assistant Surgeon. By direction of the Secretary of War the leave of absence granted him in S. O. No. 38, April 16, 1889, Division of the Missouri, is extended twenty days. Par. 2, S. O. 114, A. G. O., Washington, May 17, 1889.

STEPHENSON, WILLIAM, Captain and Assistant Surgeon. By direction of the Secretary of War is granted leave of absence for four months, with permission to go beyond sea. Par. 15, S. O. 114, A. G. O., Washington, May 17, 1889.

RAFFERTY, OGDEN, First Lieutenant and Assistant Surgeon. Granted leave of absence for one month. Par. 3, S. O. 29, Headquarters Department of Texas, San Antonio, Tex., May 13, 1889.

Official List of Changes in the Medical Corps of the United States Navy for the week ending May 18, 1889.

WHITING, ROBERT, Passed Assistant Surgeon. Ordered to the receiving-ship Minnesota.

HARMON, G. E. H., Surgeon. Detached from the Naval Academy and ordered to the Constellation.

LOWNDES, C. W. F., Assistant Surgeon. Detached from the Naval Academy and ordered to the Constellation.

ARNOLD, W. F., Assistant Surgeon. Detached from the New Hampshire and ordered to the Pinta.

RUSH, C. W., Passed Assistant Surgeon. Detached from the Pinta, to proceed home, and wait orders.

MCCLURG, W. A., Surgeon. Ordered to the Bureau of Medicine and Surgery.

STILT, E. R., Assistant Surgeon. Detached from the Bureau of Medicine and Surgery and ordered to the New Hampshire.

ECKSTEIN, H. C., Surgeon. Ordered to the Marine Rendezvous, Philadelphia, Pa.

BRADLEY, M., Medical Director. Detached from Marine Rendezvous, Philadelphia, Pa., and to continue on special duty, Philadelphia.

RUTH, M. L., Surgeon. Granted another year's leave of absence.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 18, 1889:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	19	1
Scarlet fever	185	30
Cerebro-spinal meningitis	2	2
Measles	134	5
Diphtheria	178	57
Small-pox	0	0
Yellow fever	0	0
Cholera	0	0

NARCEINE HYDROCHLORATE.—Most of the narceines of commerce are of varying constitutions; in all probability they contain foreign substances; this, at least, seems the only tenable explanation of the widely differing statements in chemical literature as to the melting of this alkaloid. While the therapeutic availability of narceine in the alkaloid form is impaired by its poor solubility (1 part in 250 of boiling water) and by the difficulty of determining its condition of purity, its hydrochloric salt is notably free from these drawbacks; and this appears, therefore, to be the most available form in which to exhibit narceine as a medicine. Chemically pure narceine hydrochlorate comes in the form of short, stout, lustrous prisms, which are soluble in all proportions in boiling water. Its solubility in cold water vastly exceeds that of the free alkaloid. The most practical solvent for the hydrochlorate is water containing a small admixture of alcohol. According to the clinical tests quoted by Erlenmeyer and Reissner, the chief special value of narceine is in its use as a sedative and hypnotic in psychiatric diseases; on which field of practice it has, in most cases, yielded results superior to those of morphine. Also for a hypnotic and sedative in general it has proved exceedingly valuable: according to Debout's reports, a dose as small as 0.03 gramme (½ grain) suffices to induce a quiet sleep without oppressive dreams, and not followed by headache on awaking. According to Oetinger, Petrini, Sichting, and others, it is highly approved in coughing-spells; and in sciatica and neuralgias is preferable to morphine.

THE EYESIGHT OF SCHOOL-CHILDREN.—Dr. De Mets, of Antwerp, has just made known the results of his examination of the eyes of the children attending the primary schools of that city. He examined 7,040 scholars and directed his attention chiefly to the state of their refraction and their chromatic sense. Their ages ranged between seven and fourteen years, so that it is not to be wondered at that he found a very small percentage of myopes among them. Only 2.13 per cent. were myopic, and of these nearly one-half had but one dioptre of myopia. Cohn, on the other hand, found 6.7 per cent. of the children in German elementary schools to be suffering from more than one dioptre of myopia. Dr. De Mets thinks that this great difference between the two countries is due to a hereditary predisposition peculiar to the race; but he also admits that the construction, furnishing, and lighting of the schools have a great influence on the development of myopia. Thus in nine girls' schools which were well lighted there was 1.74 per cent. of myopes, as against 4.83 per cent. in three schools badly lighted. And as regards boys, the figures are equally striking—viz., in nine well-lighted schools the percentage was 1.69, as against 2.67 in badly lighted buildings. Dr. Deneffe recently pointed out the superiority of the chromatic sense in woman, and Dr. De Mets' observations confirm this statement as regards female children. He thinks it is due to the fact that girls are so much more in contact with colors in their needlework, and that thus their color-sense is educated, and he thinks with Dr. Deneffe that the appreciation of colors should form part of the regular school course.—*The Lancet*, November 17, 1888.

THE FOUNDER OF THOMSONIANISM.—Thomson was a man of indomitable energy, born in the wilds of New Hampshire in 1769, before the days of medical schools, and when but few foreign drugs were imported. With the resources of a genuine Yankee, he betook himself to the woods, and made a rude study of the roots and herbs indigenous to the stubborn soil. His theory was, that all disease was owing to "canker in the stomach," and, reasoning from this, it was evident that one kind of canker caused measles, another kind caused scarlet fever, or canker-rash, and so on through the long list. These various cankers he numbered 1, 2, 3, etc., and gave to each number a specific remedy of a corresponding number. Thus, canker No. 1 must be met by lobelia; but, if the inside of the stomach was left cold, it must be warmed up by No. 2—cayenne pepper. If, during this process, the patient becomes nervous, or has convulsions, he must be treated to No. 3—nerve-root or skunk cabbage. Steaming was an adjunct in this process, and this consisted in subjecting the victim to the steam of vinegar and water. The apparatus was an open-bottomed chair, in which the patient was seated naked, but enveloped in a comforter. Underneath the chair an iron basin was placed, filled with water and vinegar, into which was plunged a red-hot stone. During this process, the poor wretch was treated to alternate doses of lobelia, cayenne pepper, or skunk cabbage, according as he was hot, cold, or "had fits." This ordeal was repeated daily, or oftener, until the subject was either cured or killed.—DR. JOHN CROWELL.

A CASE OF CICATRICIAL STENOSIS OF THE PYLORUS RELIEVED BY LORETA'S OPERATION.[1]

BY FRANCIS P. KINNICUTT, M.D.,

ATTENDING PHYSICIAN TO ST. LUKE'S HOSPITAL AND THE NEW YORK CANCER HOSPITAL,

AND

WILLIAM T. BULL, M.D.,

ATTENDING SURGEON TO ST. LUKE'S HOSPITAL, AND THE NEW YORK HOSPITAL.

ON May 26, 1888, P. S——, male, aged thirty-eight years, was admitted to my wards in St. Luke's Hospital. The patient brought a note from my colleague, Dr. William Bull, with the request for a diagnosis of his case.

Previous history.—The patient states that he enjoyed good health previous to eighteen months ago, when his digestion began to trouble him. The ingestion of food was speedily followed by distress and pain, there were acid eructations, much flatulence, and obstinate constipation. At a later period of his illness vomiting occurred, at first once in two or three days, gradually, at least once daily, the vomiting being copious in character. On numerous occasions, but not recently, the vomited matter was chiefly of a "coffee-grounds" character. He progressively lost flesh and strength, and finally was wholly incapacitated for work. He had sought relief from various sources, and had been under treatment in the Roosevelt Hospital, but with only a slight and temporary amelioration of his symptoms.

Condition on admission.—The patient has a cachectic appearance, is anæmic, poorly nourished, and weak. He vomits usually once daily; the vomited matter is copious in amount, and consists apparently of most of the food, partially digested, taken during the previous twenty-four hours. He suffers from constant epigastric distress and pain, from foul-smelling and acid eructations, and from obstinate constipation. The physical examination of heart, lungs, liver, and spleen is negative. The urine contains neither albumen, glucose, nor casts. The abdomen is distended, and the contour of the stomach is plainly visible through the thin abdominal walls. Its peristaltic movements, the waves passing from left to right, are plainly seen; loud succussion is heard not only on palpation, but on any movement of the patient. No distinct tumor is appreciable, although a sense of unusual resistance is detected over the pyloric area. Penzoldt's modification of Piorry's method was employed to demonstrate the presence of dilatation of the stomach. It consists in withdrawing the contents of the stomach by means of the œsophageal tube, and then refilling the organ with fluid. By noting the lower limit of dulness thus produced, the lower border of the stomach can be accurately determined. It was found to reach a point four and a half inches below the umbilicus in the median line. The capacity of the stomach was found to be about 2,200 ctm. The history and physical signs permitted of an easy diagnosis of dilatation of the stomach; the above described methods of investigation demonstrated the extreme degree of the dilatation. Persistent gastrectasia of this degree is produced only by pyloric stenosis, which is practically either of a cancerous or cicatricial character; cicatricial stenosis may be regarded as caused by gastric ulcer.

A differential diagnosis between the above forms is most desirable with the view to prognosis, and to surgical interference and its method. The history of the illness, the condition of the patient, the physical examination, often furnish no distinguishing points, and mistakes in diagnosis are frequently reported.[1] Since the winter of 1885 five cases of extreme gastric dilatation from pyloric stenosis have fallen under my personal care. In the first case,[2] all the symptoms and physical signs of cancer of the stomach were present in a marked degree; a pyloric tumor was easily palpated. A diagnosis of cancer was made, only palliative treatment was employed, and at the autopsy cicatricial stenosis was found to exist.[3] In the three succeeding cases,[4] which have been published, pyloric stenosis from cicatricial contraction was diagnosticated, and found on surgical exploration, or after death. In all, the presence of a pyloric tumor, of small size, was easily demonstrable. The fifth case is the subject of the present paper; a sixth, in which I believe the stenosis to be of the cicatricial form, is at present under observation.

With the view of determining the probable character of the stenosis in the present case, the contents of the stomach were submitted to a very careful chemical examination for ten consecutive days, by the methods described by me in a former issue of this journal.[5] A test meal was given to the patient daily, and the gastric contents removed, undiluted, by means of the stomach-tube, about four and a half hours later, and examined. Free hydrochloric acid was found in all the specimens; its percentage was carefully estimated, as well as the absolute acidity of the gastric contents. Table I. summarizes the results of the examinations, made by the gentlemen of the house staff, Drs. Collins, Southworth, and Vaughan, to whom I wish to express my indebtedness for their efficient assistance in my investigations.

It will be seen that the average percentage of free hydrochloric acid is about one-third less than that found in the normal stomach during digestion, which may be regarded as 0.2 per cent.

The gross or absolute acidity is that of the hydrochloric acid and the organic acids (lactic, acetic, butyric, etc.) combined, and will vary as the fermentative processes exist in greater or less degree from day to day.

The constant presence of free hydrochloric acid during digestion being demonstrated, the probable cicatricial, *non*-cancerous nature of the stenosis was diagnosticated. The diminished percentage of hydrochloric acid present inclined me to believe that the ulcer had healed, this acid being found in excess in the presence of active gastric ulceration. Its diminished secretion found an explanation in the gastric catarrh which existed.

Based upon the results of the above-described methods of investigation, a diagnosis of dilatation of the stomach from pyloric stenosis, cicatricial in character, was made, and my surgical colleague, Dr. Bull, consented to attempt to relieve the condition by Loreta's operation of digital divulsion of the pylorus.

[1] Read before the Practitioners' Society, New York, May 3, 1889.

[1] In three pylorectomies in Billroth's clinic, in 1887, the diagnosis of cancer was made; cicatricial stenosis from ulcer was found.

[2] This case was under my care before examination of the gastric contents had been undertaken by me.

The patient was transferred to the surgical wards on June 11th.

In conclusion, I desire to add a single word in regard to the present position of the question of the value of the presence or absence of hydrochloric acid in the gastric secretions, as a diagnostic sign of cancer of the stomach. The consensus of experience among clinical observers in various parts of the world is to the effect that free hydrochloric acid may be, and is, absent, temporarily or otherwise, in many gastric affections; that it is absent in a very large proportion of cases of cancer of the stomach; *that its continuous presence is a diagnostic sign of great value in excluding the probable existence of gastric cancer.* (F. P. K.)

June 11th.—The patient was prepared by emptying the bowels for two nights previous to the operation with enemata of soap-suds and castor-oil. At 12, 2, and 3 o'clock the stomach was washed out with warm water. Ether was administered at 3.30 P.M. No tumor could be felt. The incision was parallel to the border of the costal cartilages on the right side, five inches in length, extending from one and one-half inch below the ensiform appendix to the level of the tenth costal cartilage. In opening the abdomen the right and left lobes of the liver appeared, and in pressing them back with a sponge, the pylorus and duodenum were seen. In order to draw the pylorus into the wound the incision was lengthened one inch downward and outward. There were no adhesions, nor was the pylorus abnormally thickened, but at its junction with the gastro-hepatic omentum there was an area as large as the top of a lead pencil, where its peritoneal coat was thicker than normal and drawn into several stellate folds. After surrounding the pylorus with several sponges, an incision two inches long was made into the anterior wall of the stomach at a distance of two inches from the pyloric orifice. The edges of the wound required five or six cat gut ligatures. No fluid escaped from the stomach. Some time was spent in finding the pyloric orifice, on account of its small size. The lumen admitted a rubber urethral bougie of 20 French urethral scale, but it was thoroughly seen only after retracting the edges of the stomach-wound. Opposite the site of the stellate cicatrix before mentioned there was a small area of gray cicatricial tissue, chiefly on the upper wall, and half surrounding the lumen of the contracted orifice. This opening was then slowly dilated by introducing œsophageal and rectal bougies till No. 6 Wales rectal bougie had been passed, measuring one-third of an inch in diameter. The little finger, index, and middle fingers were introduced, and followed by rectal bougies up to No. 11, measuring a little over one inch in diameter. Then the two index-fingers were inserted and slowly separated till an interval of one-half inch existed at their tips. The walls of the pylorus were then quite flaccid, and its lumen about two inches in diameter. There was no tearing of the mucous membrane, and no noticeable bleeding; but there was so much resistance when this degree of dilatation was reached that I thought it not prudent to stretch further. A continuous catgut suture through mucous membrane and twenty silk Lembert sutures closed the stomach wound. No blood or gastric fluid had passed beyond the barrier of sponges. The line of sutures was dusted with iodoform, and the abdominal wound washed with boracic acid solution, and closed with catgut and two silver-wire relaxation sutures, over a small catgut drain between the peritoneum and muscles. Bichloride gauze dressing. The duration of the operation was two hours and ten minutes, and the patient's general condition underwent no perceptible change during its performance.

For the next forty-eight hours rectal nutrient enemata were given every six hours and retained. There was no pain, and no constitutional disturbance. On the third day ice, beef-tea, and milk were given frequently in small quantities by mouth. A large fecal movement was passed. On the sixth day chicken broth was given by mouth, and the dressing was removed and primary union without suppuration had occurred. On June 19th, the ninth day after operation, he was transferred to the medical wards. (W. T. B.)

On readmission to the medical wards the patient's general condition was excellent. Milk, the white of raw egg, and animal broths were digested without any sense of discomfort; there were voluntary movements of the bowels, and an increase in weight began almost immediately. On the 26th scraped meat was ordered, and on the 28th toast and lightly boiled eggs, and from this date the dietary was enlarged daily until the ordinary hospital diet was allowed.

Digestion was unattended with a single symptom of discomfort, and on July 31st the patient was discharged, apparently well, having gained fifteen pounds in weight from the date of the operation.

During the late summer, owing to imprudences in diet, there was a recurrence of some disturbance of digestion and he was readmitted to the hospital. A regulation of the diet, with the correction of constipation which existed, afforded relief, and since this date the patient, on an ordinary diet, has been quite free from his former symptoms, with the exception of a tendency to constipation. He finds, however, that he is obliged to exercise caution in the use of "sweets." His nutrition is satisfactory and his general condition excellent. A careful examination shows that the dilatation of the stomach has very sensibly decreased, the lower boundary reaching a point two inches below the umbilicus in the median line. The question arises, whether the continued dilatation results from a partial recontraction of the pyloric stricture, or is simply the result of the great distention of the stomach produced by the old and long-continued stenosis. The marked diminution in its size present eleven months after the operation, leads me to believe that the latter may be the correct explanation, and to hope for still further improvement. (F. P. K.)

At the time this patient presented himself for treatment Loreta's operation seemed to me to offer the best chance of relief or cure, with the least risk to life. All the data accessible to me were in favor of it; and several writers (Holmes, Smith, and McBurney) had expressed the opinion that it should have preference over other procedures. Up to 1886, pylorectomy in over 100 cases, 25 of which were for cicatricial stenosis, had a mortality of fifty per cent. for these and seventy-five per cent. for cancerous strictures; gastro-enterostomy had been followed by almost as bad results, and duodenostomy had resulted fatally in three instances (Winslow: *American Journal of the Medical Sciences*, April, 1885). This man's rapid recovery without the slightest accident, and his present good condition, eleven months after operation, are valuable evidence in favor of this procedure. But we need more cases before we can assign it its proper place. A careful search by Dr. T. C. Hasson has brought to light nineteen other operations, which I present to you in tabular form, and regretting that I cannot give fuller details of many of them (Table II.).

TABLE II.—*Table of Cases of Digital Divulsion of the Pylorus.*

No.	Operator.	Date of operation.	Sex and age.	General health and duration of symptoms.	Results.	Remarks.	Reference.
1	Loreta	Bologna, September 14, 1882.	M., 47..	Suffered for twenty years; pain in stomach, vomiting, vomited matter sometimes contained blood; emaciation.	Cured		Loreta, Divulsione digitale de piloro. 2d edition, p. 64. Bologna, Fratelli Frères, publishers.
2	Loreta	December 22, 1882...	M., 18..	Suffered for seven years; feeling of weight in epigastric region, vomited daily, vomited blood several times.	Cured		Idem.
3	Mario Giommi..	February, 1883.....	F., ?...	?...	Died		Quoted by Loreta.
4	Cattini	Florence.....	F., 30..	Suffered for three years with symptoms of stenosis.	Cured		Idem.
5	Loreta	March 17, 1883.....	M., 46..	Suffered seventeen years; chronic gastritis; bloody vomiting.	Died	Collapse	Quoted from Winslow. American Journal of the Medical Sciences, April, 1885.

7	Frattini	Venice, June 9, 1884.	? ?...	Symptoms not given.....	Cured		Quoted by Holmes in British Med. Jour., 1885, vol. i., p. 375.
8	McBurney.....	New York, July 6, 1885.	F., 39..	Attacks of vomiting for nineteen years; within one year daily vomiting; pain in epigastrium; no blood vomited; physical signs of extreme dilatation of stomach.	Died in six hours..	Stomach found filled with blood. Blood in duodenum and small intestines. Tear in mucous membrane of pylorus.	Annals of Surgery, 1886, p. 372 et seq.
9	McBurney.....	New York, July 6, 1885.	F., 52..	Symptoms of ulcer twenty years previous; present symptoms for eighteen months; much emaciation; severe abdominal pains; vomits daily; sometimes vomits blood; physical signs of great dilatation of stomach.	Died in thirty hours from suppression of urine.	At autopsy advanced Bright's disease found, also ulcer of pylorus.	Idem.
10	Molière	Lyons, 1886.....	F., 47..	Suffered for one year; pain in epigastric region; loss of appetite, vomiting, no blood vomited; large tumor in region of umbilicus, three months' standing.	Died on eighteenth day from exhaustion, without having vomited once.	The case was diagnosed as cancer, and proved so at autopsy. Was thought that operation would give patient relief.	Reported by Bertoye in Lyon Medical, 1886, vol. lii.
11	Haggard	Hull, March, 1886...	F., 51..	Symptoms of gastric disturbance for five years; stomach dilated; vomited daily, though no blood.	Cured	Stomach still dilated at last reports.	British Medical Journal, February 19, 1887.
12	J. M. Barton ...	Philadelphia, May 22, 1887.	M., 58..	Symptoms of pyloric obstruction one year duration; no vomiting of blood; much exhaustion	Died on fourth day from exhaustion.	Dr. Barton says patient was operated on too late.	Philadelphia Medical Times, 1887–88.
13	Loreta	Bologna, September 14, 1887	F., 47..	Loss of appetite eight years previous, after an attack of typhoid fever; since one year pain in epigastric region; vomiting, constipation.	Died on fifth day; tetanus.	Patient had opisthotonos for several hours before death. No autopsy.	Gazetta degli Ospitali, 1887, Nos. 101.
14	Loreta	October 13, 1887....	F., 31..	Five years dyspeptic symptoms; constipation for one year; pain in stomach, and vomiting after meals.	Cured		Gazetta degli Ospitali. 1887, No. 101.
15	Loreta	October 31, 1887.....	M., 34..	For twelve years pain after meals, and regurgitation of food; vomits now without pain..	Cured		Idem.
16	Brichetti.....	Bologna, December 19, 1887.	M., 24 .	No history given	Patient doing well on sixth day.		Gazetta degli Ospitali, December 25, 1887.
17	Loreta	January 30, 1888....	M., 54..	Dyspeptic symptoms for ten years; since one year vomited after each meal; much pain; loss of weight.	Improved.....	Gained weight for some months, but symptoms returned.	Gazetta degli Ospitali, September, 1888.
18	Loreta	June 20, 1888.....	Above mentioned patient.	Symptoms returned two months after operation, but not so severe.	Cured	Patient left hospital two months later perfectly well.	Gazetta degli Ospitali, September, 1888.
19	Loreta	July 12, 1888.....	F., 22..	Gastric trouble for five years; pain after meals; vomited for only four months; no blood.	Cured	Duodenum and pylorus found adherent to liver. Adhesions tied off.	Reported by Codarilla in Gazetta degli Ospitali, September 16, 1888.
20	Bull.....	June 11, 1888.....	M., 38..	For twenty months pain in stomach; daily vomiting; constipation; marked dilatation of stomach.	Cured		Details in paper preceding.

Of the twenty cases here presented two should be excluded, one because the condition was carcinoma, the other because it was reported on the sixth day. This leaves eighteen operations, with twelve recoveries and six deaths, a mortality of 33.3 per cent. The causes of death are hemorrhage into stomach after operation, renal disease, exhaustion, tetanus, collapse, one each, and in one case it is not given. Of these the first is the only one inherent to the operation itself, and suggests the necessity of great caution in stretching the narrowed orifice. (In my own case I took care to do this very slowly, consuming fifteen or twenty minutes in this stage of the operation.)

A question that naturally arises is, whether the overstretching of this cicatrix will be followed by recontraction. It is unfortunate that the published records give us no information except in one instance (Case 17), where the operation was followed after two months by return of symptoms caused by recontraction. Professor Loreta himself has kindly written me that he has observed this in three instances, one of which is doubtless the case referred to. His letter bears on other points of interest, and therefore I present it in full. It is dated Bologna, February 20, 1889, and is translated by Dr. G. G. Van Schaick as follows:

"I cannot tell you the exact number of patients operated on by me by divulsion of the pylorus, because, unfortunately, a good part of the notes I had taken to serve for the statistics of this operation have been lost.

"The last 7 patients which I operated on, in 1887 and 1888, gave a result of 5 cures and 2 deaths. Of the two that died, one did so from hemorrhage; the blood flowed from the edges of the gastric incision for the reason that the suture was not sufficiently tight to serve as a hæmostatic. The other died of peritonitis, the peritoneum having been lacerated at a point of the dilated ring without my having noticed it.

"I saw relapses of the contracture three times in other cases; of which two were in women and one in a man. I have noticed that the return of the contracture and of the symptoms due to it have always shown themselves a short time after the operation, or about two or three weeks after, as a rule, and this occurred every time that the dilating force had not completely paralyzed the cicatricial tissue, and hence had not brought about its immediate adipose degeneration. Of these three cases two underwent an operation for the second time, with permanent benefit.

"In the few patients that I have been able to observe some months or years after the operation, I have been able to establish the fact that, as it resumed its normal function, the stomach became a great deal smaller."

The foregoing facts will be of some use in enabling us to give to Loreta's operation its proper status as com-

pared with other procedures. It has certainly had a greater mortality than has hitherto been supposed. There is shown to be danger of hemorrhage from tearing the mucous membrane in dilating the orifice, and of peritonitis from tearing through the peritoneal coat. It is evidently a procedure that must be gradually. even if forcibly, performed in order to avoid these accidents. It is uncertain or unknown in what proportion of cases recontraction will follow. There are the same sources of failure due to the patient's exhausted condition, or the existence of other visceral disease that attend other abdominal operations. But with all these risks and uncertainties, it is certainly to be preferred to pylorectomy. This is the most perfect operative procedure, but it is as yet too dangerous. Gastro-enterostomy, or the formation of an anastomosis between the stomach and upper jejunum, bids fair to show better results than hitherto, since the improvements in technique afforded by Sena's plates and Abbé's catgut rings have been adopted satisfactorily. It may yet be shown to be the safest procedure. Another method is in its infancy, and yet seems worthy of trial. It is called "pyloroplasty" by Mickulicz, who describes it in the *Archiv. für Klin. Chirurgie*, vol. xxvii., page 79. He reports a case, which ended, however, fatally, fifty hours after operation, from exhaustion and beginning peritonitis. Here the stenosis was accompanied by an ulcer, the bleeding from which was the chief indication for operation. The pylorus was laid open by a longitudinal incision, the ulcer cauterized, and the incision united with sutures in a transverse direction. This gave to the orifice, which, when opened, was contracted so as to admit only a dressing-forceps, a lumen which admitted the index-finger readily. The operation was performed in February, 1887. Eleven months before this, Heincke, as narrated by Mickulicz, had performed a similar operation and with success. Four months and a half after the operation the functions of the stomach were well performed, the patient had gained greatly in weight, and the dilatation had diminished. (W. T. B.)

THE COST OF YELLOW FEVER EPIDEMICS—THE EPIDEMIC AT DECATUR, ALA., IN 1888,[1]

By W. E. FOREST, M.D.,

NEW YORK.

YELLOW FEVER is an American disease. It is claimed that it originated on the west coast of Africa, but whether this be true or not, it is now, like the negro, thoroughly at home on the Western Continent. Its habitat is the eastern coast of the Spanish Americas, between about the 23° north, and the 20° south, latitude. From these regions it may and does, under favorable conditions, extend to the countries to the north and south.

The United States has suffered more by far, in modern times, from this pestilence than any other country, hence there are good reasons why physicians and sanitarians of this country should study this disease. There is a particular reason why our attention should be turned to it at the present time, because of the severe epidemic in Florida that has so recently attracted the attention of the civilized world, and drawn from all sections of this country sympathy and aid.

Of yet more importance is the fact that the coming season may witness a far more disastrous epidemic than that of the past, for there are those that assert, and not without reason, that the wave of this disease that extended over Florida last season, and sent a ripple into North Alabama, may, the coming summer, spread over a large area of the country, and be as severe as the famous epidemic of 1878. It is important, then, that steps be taken while there is time to meet this threatened danger.

The present paper is based upon observations made during a personal experience with this pestilence last season, and upon the subsequent study of the history of the fever as it has appeared in the United States and Europe at different times in the past.

Before entering upon the history of the epidemic I witnessed at Decatur, Ala., let me speak briefly upon the vast losses that are occasioned by yellow fever epidemics.

The loss of life, if the epidemic be at all general in character, is simply appalling. Thus in the epidemic of 1878, which was confined for the most part to three sparsely settled States—namely, Mississippi, Louisiana, and Tennessee, whose combined population was less than that of New York City—there were some one hundred and eighty thousand cases of the disease, and over twenty thousand deaths. This great calamity occurred in the space of about nine weeks. The loss of life was not distributed uniformly over the area of the three States mentioned, but was most marked in certain sections, where, indeed, the pestilence ceased only when all subjects were exhausted, as a fire dies out for want of fuel. Thus in Memphis, where some nineteen thousand people remained in the city, there were five thousand one hundred and fifty deaths, and seventeen thousand six hundred cases of the disease altogether. Sixty per cent. of the white people in the city died. Smaller communities, such as Holly Springs, Grenada, Greenville, and other places, suffered as greatly in proportion.

Norfolk, in the epidemic of 1855, had over ten thousand cases of the fever; more than fifty per cent. of the population remaining in the city died. Other sections of the country, besides the South, have suffered from this disease, and other countries as well. Thus Philadelphia, then a small city of some fifty thousand inhabitants, lost ten thousand and thirty-eight of her citizens from yellow fever, from the three epidemics that occurred between the years 1793 and 1800, a period of seven years. The province of Andalusia, in Spain, in the year 1800, had sixty-one thousand deaths from this disease. The city of New York, and many of the New England cities, have suffered time and again from this pestilence.

When we come to consider the pecuniary loss occasioned by yellow fever it is difficult to get accurate figures, but the "Annual Encyclopædia" for 1878 estimates the loss to the South from the pestilence of that year as exceeding two hundred million dollars. This, of course, includes losses from the prostration of business, depreciation of the values in property, etc.

The epidemic of the year just passed has been very limited in character, but has disturbed business over a very large section of the South, and thus caused great loss. One of the modern phases of yellow fever is that the outbreak, even though very local in character, causes widespread panic, and the establishment of quarantines that disturb trade and commerce very seriously. Thus the announcement of one or two cases of the disease in the little city of Decatur, in North Alabama, and the discovery of one or two suspicious cases in Jackson, Miss., threw the inhabitants of several neighboring States into a panic that was almost hysterical in character. It is estimated that fifty thousand people fled from their homes to the North through fear of the disease and the quarantines.

The Relief Association, at Jacksonville alone, last season spent nearly a half million dollars. All but a very small part of this sum was contributed by the charitably inclined throughout the country and the General Government.

Great as have been the losses in this country in the past from this disease, the losses in the future, if an epidemic shall become again general in character, will be enormously greater. This will arise from the developments that are taking place so rapidly in the South. How great this development has been may be estimated from the single item of railroad growth in this section during the last decade. It is estimated that seven hundred million dollars have been invested in railroads since the epi-

[1] Read before the Public Health Section of New York Academy, March 1, 1889.

demic of 1878. Progress in other lines has kept pace with this branch. The South has entered upon a period of rapid industrial growth that gives rise to the development of cities and villages.

Now, it is well known that yellow fever is an urban disease, prevailing almost exclusively in cities and villages. The developments in the South have been so extensive in the last five years that it would be a moderate estimate to say that an epidemic the coming season, no more extended than that of eleven years ago, would cause the loss of five hundred million dollars and not far short of fifty thousand lives.

Strangely enough, these Southern developments, in a certain section, have greatly increased the dangers of yellow-fever invasions of this country. I refer to the opening up and growth in population in Southern Florida. It cannot escape the observer that the climate and general conditions in Southern Florida are not essentially different from those in Cuba, where the disease is ever present. Hence there seems to be no reason in the nature of things why this disease may not become endemic in the former locality as it is in the West Indies to-day. This region, Southern Florida, it is claimed, is perpetually below the frost line, the only agent that is known to destroy the germs of the disease, and hence here will be an excellent winter home for consumptives and yellow-fever microbes. From this section the disease will be ready to follow the lines of travel, in the spring and summer, into the States north and west of Florida. That this danger is not an imaginary one, may be known from the fact that it was in this region the disease wintered in 1887, and from here extended to North Florida and Alabama.

From the foregoing a faint estimate of the losses to life and property from yellow fever may be obtained and the importance of the subject under consideration estimated.

It would seem that, with a danger such as this hanging over the country, not physicians and sanitarians alone, but the press and the public would awake to the momentousness of the subject, and that Congress could be induced to appropriate a small portion of the surplus millions in the Treasury to meet this danger.

Great as is the calamity from an epidemic of this kind it is not one of those mysterious visitations of Providence, like an earthquake for instance, that cannot be guarded against. It is rather a scourge that visits the human race, especially in this country, as a punishment for broken sanitary laws. There is no epidemic disease that can be more easily prevented, and none more readily stamped out than yellow fever. Spain is no longer ravaged with this disease, owing to proper quarantine regulations; and there is now little fear that Philadelphia will again lose one-fourth of her population, as she did in the past, from this pestilence, because she now has better sanitary laws.

Having thus touched upon the great losses occasioned by the disease under consideration, we come to the second part of our subject—a brief history of the epidemic at Decatur, Ala., during the season just passed.

It is nearly impossible to devise practical means to prevent or stamp out a yellow-fever epidemic without having had a personal experience with the disease. One soon sees that we have not only to manage an epidemic disease as it manifests itself in a community, but deal with a community struggling with an epidemic. In other words, we have to deal with the passions of fear, greed, and a sort of fatalism, in a people ravaged by a pestilence, as well as with the disease itself. My meaning will appear in the following history, where I have dwelt, not upon the dramatic or pathetic features of the epidemic, but upon those that illustrate the origin and spread of the disease.

It is of interest, first, to trace the steps by which the fever found its way from its home in Havana, Cuba, to a little city in north Alabama.

Early in 1887 a family moved from Havana to Key West, Fla. As the regular line of steamers would not transport household goods at that time of the year, on account of the fever in Havana, the family took passage on the "tramp" steamer Cochran, and landed their infected baggage in the city. The result was a severe epidemic in Key West. All the towns in Florida quarantined against Key West, Tampa among the others. In the latter city were a family of Italian fruit-dealers, named Turk, who at once began to smuggle fruit from Key West to Tampa. On one of their expeditions they brought in a few woollen blankets, and with them, of course, the germs of the dreaded disease.

Tampa thus had its epidemic. It commenced at the house of the smugglers. Quarantine was declared against Tampa, and the Government Marine Hospital officers were sent down to assist the County Health Board in maintaining strict quarantine. The Health Board raised the quarantine early in December, in deference to popular clamor, although the disease still existed at Tampa. The result was that the fever spread to Plant City and Manatee, and thus as early as February reached Jacksonville. Here it ran a mild course in the cool weather of the early spring and summer under the name of "society fever." It was not until August that the authorities there would admit that yellow fever was in the city.

In fact, several prominent property-holders will not admit yet that the disease has been there. On the 14th of August a man named Livingstone packed his carpet-bag with infected clothing, and, with a liberal supply of the germs in his system, started for Decatur, Ala., where he had an acquaintance.

With but little difficulty he passed the quarantine stations, and the inspection of the numerous quarantine officers stationed at the different towns. At one place he was put off the cars, but he drove across country to another station and continued his journey without further hinderance. To be sure, he had to resort to falsehoods, and the tricks that refugees commonly employ; but on the 17th he reached Decatur with his yellow-fever germs. The following day he had the symptoms that herald an attack of the fever. It was an exceptionally mild case, such as prevailed at Jacksonville, and he did not take to bed with it. It will be noticed later that the type of the epidemic he gave rise to at Decatur was not a mild one, but, on the contrary, exceedingly malignant.

Two days after his arrival the city authorities ordered him to leave town. He did so, protesting to the last that he had not been at Jacksonville within three weeks, and that he was now in perfect health. He has but lately furnished the above particulars to Dr. Wall, of Tampa.

From Decatur the refugee, still with the fever upon him, went to Florence, Ala., then to Memphis, and at last to Hot Springs, Ark. He thus spread the germs of the fever over a large area of country, but at no place, except Decatur, did the seeds happen to fall upon suitable soil. The conditions at Decatur were peculiar. The Spencer House, where the refugee lodged, had been closed all summer, and the house was damp and musty; again, there had been an unusual amount of rain and excessive heat during the summer; then, too, this being a "booming town," there had been much stirring of the soil in grading streets in the neighborhood of the Spencer House.

Thus the conditions for the growth and multiplication of yellow-fever microbes were all present, especially as there was then no sewerage system at this house, and the ground was of necessity saturated with human excreta. It is very possible that there was not another house in the city where the germs would have developed so as to cause an epidemic.

About twenty days after the expulsion of the refugee his host, Spencer, took sick. All thoughts of the refugee and fears of the fever from him had long been laid aside; this case was thought to be a "remittent fever" and the patient was treated accordingly. Not a suspicion of the true state of the case crossed the attending physician's mind, at least until the last day of his patient's life, when symptoms of "black vomit" appeared. Then the local

health officer was called in. Meantime the public was in blissful ignorance of there being a suspicious case in the city until it was aroused the same day by a rather dramatic incident. Spencer lived on the main business street of the town, and just before dark, while the streets were full of people and the patient was alone with his wife, he went into violent convulsions. The faithful wife in her fright ran out on the veranda and screamed for help. Help came in the shape of every man and boy in the vicinity, and in a moment or two the house and front yard were well filled with spectators. While some were holding the struggling man the "black vomit" began again, and a physician, who had dropped in among the others, remarked "That looks like yellow fever." The volunteers, or the most of them, left the place quite as quickly as they had assembled, and in a very short time it was known throughout the city that there was a possible case of yellow fever in town and great excitement ensued. Some of the more timid left the city that night.

This seemingly trivial incident is of much importance in its bearing on the epidemic at Decatur, for the reason that it drew wide-spread public attention and alarm to the first case of the disease. A strong light was turned upon the epidemic at the outset, which should have brought about measures to strangle it at its birth. It is the usual history of these epidemics that the advent is so insidious that a number of cases—from five to twenty—have developed and been treated for remittent, or bilious, or congestive, or "prevailing," or "society" fever, before it is discovered that the disease is the dread "yellow jack." By the time this discovery is made the infection has extended over quite a space. But at Decatur this was not the case—the death-rate for fifteen days prior to Spencer's death and the amount of sickness had been unusually low, much less than during the preceding part of the summer, and there was absolutely no reason for supposing that Spencer's case was not the first case of yellow fever in the community. Could there have been a more favorable opportunity for stamping out an epidemic at its very birth than this, if the proper steps could have been promptly taken? Another fact that this case should have shown was, that there was now an "infected centre" at Spencer's house. Had he developed the disease within five days of the departure of the refugee it might have been thought that Spencer had contracted the disease from his friend's baggage direct, and that the germs had not obtained a foothold yet in the town. But the Spencer case, occurring twenty days after the visit, proved beyond a doubt that the seeds of the disease had been brought there, planted, found congenial soil, multiplied, and now were bearing their legitimate fruit. There could be no question, then, that if Spencer's case was yellow fever, Spencer's house, and the premises all about it, were badly infected and was the breeding-place of the disease from which it might extend over the community.

Now let us see what followed the discovery of this first case of the fever. The Local Health Officer very properly telegraphed the State Health Officer, and the latter reached Decatur the next day. Meantime Spencer had died, in fact he never came out of his convulsions.

With the State Health Officer came three physicians from the towns adjacent to Decatur. No one of the physicians, except the State Health Officer, could be at all considered as an expert in yellow-fever cases. An autopsy was held, and the result of the autopsy was that the four physicians that did not live at Decatur voted the case to be yellow fever; but of the ten Decatur physicians nine voted that it was not yellow fever, and one was non-committal. Thus the first step taken toward stamping out the disease was a controversy as to whether or not the disease was present. The town was divided into two hostile camps and all action was paralyzed. Those of the citizens who believed that the outside physicians might be right in their conjecture left the town in a panic that alarmed all the country around. It was estimated that three thousand people fled from the town in the next thirty-six hours. The refugees crowded the cars as fast as they could be brought in; they clung on the platforms, climbed on the roofs, and swarmed into the baggage cars. Freight trains had to be pressed into service, and delicate ladies were seen crowded upon open cars with their children and goods about them. Hundreds of families streamed out into the country on every form of vehicle that could carry a family and cooking utensils, and there took possession of all empty houses, log-cabins, and unused gin-houses that could be hired.

This left in town only those who asserted in emphatic language that there was no yellow fever there, nor had there been any, and that those who maintained that there was were no better than they should be. In fact, a mass-meeting was held five days after Spencer's death, presided over by leading citizens, at which resolutions to the above effect were passed and published far and wide.

These matters are mentioned here, not to cast discredit or ridicule upon those physicians or citizens of Decatur who stood out against the possibility of yellow fever being present. These men were earnest and conscientious in their beliefs, and when at length their mistake was apparent, came forward manfully and acknowledged it, and fought the epidemic like heroes. Decatur was not peculiar in this matter of refusing to believe she had yellow fever in her midst. Every community, almost without exception, has been equally vehement in its denials at the outset of the disease.

These matters are mentioned to show that, in order to deal successfully with an epidemic of this kind, we have to deal with human nature as well as with the scourge. Now no fact about human nature is better known than that we are loath to accept views that are contrary to our wishes. The human mind sees plainly, and with full force, the arguments that agree with its views and desires, but not so plainly those that are disagreeable and disturbing. It is small wonder, then, that the citizens of Decatur refused to accept the dicta of three or four physicians from neighboring towns in a matter that would cause the loss of hundreds of thousands of dollars from mere fright, panic, and quarantine, when their own physicians, almost to a man, took the opposite view.

And as for the local physicians, was there no good reason for their declining to adopt the view of the State Health Officer in this case? Let it be remembered that yellow fever is not a disease easy to diagnose at the outbreak of an epidemic; that at the epidemic on Governor's Island, for instance, in New York harbor, there had been *seventeen* cases of the disease before it was believed to be yellow fever; that the same is true of the beginning of al most every epidemic of this disease; that there is nothing absolutely characteristic of the disease revealed by an autopsy, except, possibly, to experts. Now, under the circumstances, with but a single case to judge from, can it be wondered at that the local physicians hesitated to give in their adhesion to views which, if erroneous, would cause them to be denounced by the community as fools and frauds?

These are some of the difficulties that will forever stand in the way of cities, or even States, dealing promptly and vigorously with a yellow-fever epidemic, so as to check it at the outset. Such questions can be handled properly only when all the authority and means of the General Government are brought to bear upon them. Had a board of Government experts been called in to investigate the Spencer case, they having abundant means and great prestige, can there be a doubt that the community that rejected the dicta of physicians from neighboring towns would have accepted the views of the Government experts, and that the Decatur epidemic would have been a thing that might have been, but was not?

Meantime, while this controversy had been in progress, the enemy had been entrenching himself in the community.

The second death from the fever was a man named Pogue, who had left Decatur in apparent health just after

Spencer had become sick, had gone to western North Carolina, and had there died of "black vomit" the day after Spencer died in Decatur. This man had been in and about the Spencer house very freely. His case was not known at Decatur until sometime later. The third case was a telegraph operator, who lived about two hundred feet west of the Spencer house. He died five days after Spencer, but he was not thought to have had the fever, but some form of kidney disease. He had a public funeral, attended by the members of the beneficiary order to which he belonged.

Meantime the physician who had attended Spencer, living about two hundred feet northwest from him; the neighbor woman who had helped to nurse Spencer, living opposite; a young man living on the corner of the next block east, and one or two others in the immediate vicinity of Spencer's house were sick, but none were thought to have yellow fever. There were thus cases on three sides of Spencer's house. This was the state of affairs when I reached the town, six days after Spencer's death. I was not an expert, had little but a theoretical knowledge of the disease, but went there to look after certain interests of my own, and to offer my services if they should be needed.

With the consent of the physicians I examined all the sick, principally for my own satisfaction. There was one, at least, that was a typical yellow-fever case, that of the physician who had attended Spencer. Not a single symptom of the disease was lacking. He was being treated, however, for "rheumatoid fever." Other cases were very suspicious, and, on the whole, taking all the circumstances into consideration, there could be no question that an epidemic was at hand. At my suggestion the physicians held a meeting to talk over the matter, and all but one were now willing to admit the facts.

Had anyone with authority and means been present now, this being the eighth day since Spencer's death, the epidemic might have been easily stamped out. All opposition on the part of the local physicians and the citizens was withdrawn (indeed most of the people now left the city on special locked trains run North). The infection had not extended more than three hundred feet in any direction from the original centre, and it would not have been a difficult matter to confine it there, and thus have brought the epidemic to a close within two weeks, with the loss of not more than two or three lives. How this could have been done will appear later. That it was not done is evident enough. The local officials seemed waiting for the State Health Officer to do something or make some suggestion. The State official, either mindful of the abuse heaped upon him a few days before, or doubtful whether he had the authority or could command the means, made no vigorous moves. Thus the enemy was practically undisturbed, and an epidemic that cost many lives and caused enormous loss ran its course.

I have said that all the cases were yet within three hundred feet of the starting-point, showing that but a small area was infected. There was a single exception to this statement, and, like exceptions, served to prove the rule that there is usually but one infected centre. One man named Falkenburgh, living some four blocks from the Spencer house was sick, but was not, when I saw him, a typical case of the disease. He had been much in the neighborhood of the Spencer house after the latter's death, and had been most outspoken against the disease being yellow fever. He undoubtedly contracted the disease there. He was sick, and died in his own house four blocks away, but there is no evidence that a single person took the disease from him or his premises. His house was not in the infected district, did not become infected by his sickness and death there, and it was several weeks before the infection, travelling slowly from house to house from the centre, reached that neighborhood. Even then it reached the vicinity in a roundabout course, coming in from the rear rather than moving in a direct line along Bank Street.

The epidemic now followed the usual course. Every day the area of infection was a little more extended, but for some time confining itself mostly to two streets running east and west, Lafayette and Vine, and to the cross streets opening into these. Cases would appear in different parts of the city, off the line, but they were always found to be people who had been in the infected area nursing, or as night watchmen and policemen, or quite often colored people who had taken home the clothes of the sick to wash them.

The nurses were allowed to mingle freely with the citizens in the uninfected part of the town, and many of the attendants developed the disease and were sick away from the infected portion of the city; but I did not observe that any new centres of infection were set up from these cases. On the contrary, the infection seemed to spread from the original centre only, much as oil dropped on water continually enlarges its area. The progress of the infection was slow, not averaging more than fifty feet per day in its rate of travel.

This is the average rate of the spread of yellow fever infection. It does not fly through the air from point to point, but slowly creeps along the surface of the ground from house to house, and may often be turned aside by an obstruction, such as a board fence, as was the case at Mobile, or a high bank, as at Memphis. At Norfolk it took the infection more than two months to travel across the city, a distance of a mile and a half. In the New York epidemic of 1822, commencing at the foot of Rector Street, the infection only averaged thirty feet per day in its spread.

The spread at Decatur was not uniform in all directions, for here and there a small district would be unaffected for a time. The disease never, however, reached the new part of the town which surrounds the old town on three sides. The reason for this is obvious. Between the old and the new parts there is a broad space of ground, from a quarter to half a mile in width, that is not built upon. There being few or no houses over this space, no sewers, or outhouses, or human excreta and filth in the soil to make a suitable nidus for the germs, they could not spread over this barrier. On the outer sides of this space were stationed guards, that to a certain extent limited the intercourse between the new and the old parts of the city. Thus the transportation of infected baggage and clothing was prevented. By these means, principally by the former, the disease, except in two or three instances, was confined to the old town. In the three instances mentioned, the disease was contracted by the parties working in the infected district.

The physicians suffered from the disease among the first, and were sorely afflicted. They were, of course, in the infected district during the day, and most of them slept in the midst of it at night. The result was that in three weeks seven of the ten were down with the disease, and four of them were dead. Before the epidemic closed the rest of those who remained day and night in the infected district, with the exception of one who had previously had an attack, came down with the disease. Of the nine affected five died. The mortality among them was thus as great as among the volunteer physicians at Memphis in 1878.

I know not where in the records of history a more heroic spirit was ever displayed than by the physicians who remained to fight the disease at Decatur. They quietly made their preparations for the worst that can happen to mortal man, and then went as cheerfully about their work as if engaged in duties devoid of all personal danger. As one after another succumbed to the disease and laid down his work the survivors took up the burden of the fallen comrade and went calmly on without fear or hesitation. Need it be said in addition that these gentlemen were serving without hope of pay or fame, content to tread the path of simple duty though it led straight down into the valley of death. The words of praise bestowed upon the physicians of the infected district of Decatur might with equal justice be applied to many more heroic

souls there; those, too, in all professions and walks of life.

I can speak thus freely of the merits and devotion of the physicians of Decatur because I was an outsider; only taking part as the others gave out.

The mortality at Decatur among the sick was very high, especially in the first part of the epidemic. It averaged, for a time, among all classes, about fifty per cent., but later the death-rate fell, so that the general average was about thirty per cent. Of course it was very much higher in the white race than in the colored. The latter race seems nearly as susceptible to the infection as do the whites, but the disease is not nearly so fatal among them. The rate of mortality at Decatur was markedly in excess of that at Jacksonville, it will be noticed. At the latter place the death-rate was less than ten per cent. At Memphis, in 1878, the general rate of mortality was thirty-nine per cent., but among the whites alone it was seventy per cent., while among the colored only eight per cent.

The influence of frost in checking the disease was very marked. The first considerable white frost nearly exterminated the germs, or at least it checked their activity. This was followed by a period of warm, muggy weather, when the disease became again active. Indeed it required quite a hard freeze to finally put an end to the epidemic.

Sunlight direct, and moving currents of air likewise lessen the activity of the yellow-fever germs. Thus there seemed to be but little danger for anyone to enter the infected district for a few hours in the middle of sunny days. The danger was much increased in dark, muggy, or rainy days, and at night the danger was very great. Nearly, if not all, the night-watchmen and policemen in the infected district came down, often after a very short exposure.

Two facts of immense importance were clear to my mind from a study of the epidemic at Decatur. These observations are not new, they are recognized by all who have made a study of these epidemics, and yet the medical profession, for the most part, and notably the public at large, seem ignorant of them.

A knowledge of these two facts, however, will enable us to stamp out at the outset any yellow-fever epidemic that may appear in this country.

1. Yellow fever is not a contagious disease; that is, it cannot ordinarily be communicated from person to person as is the case, for instance, with small-pox.

2. It is a highly infectious disease; that is, the place, the locality where the germs are growing and multiplying, is exceedingly dangerous.

Remove the yellow-fever patient from the infected district, and he is as harmless to those about him as if he had nothing more dangerous than a broken arm.

The "infected district," though every case of fever may have been removed, is none the less dangerous to those entering it.

Let me mention a few facts to show that the disease is not contagious when ordinary cleanliness is observed in the care of the patient.

No less than twelve of the Decatur refugees came down with the fever after leaving the infected district, some of them in towns and villages but a few miles distant. These people were attended and cared for by unprotected nurses and physicians, but no one took the disease from them.

The report of the epidemic at Norfolk, in 1855, says: "In no case that we have known or heard of was there the least reason to suspect that the disease was contagious. Many hundreds of our people, flying from the pestilence, sickened and died in the neighboring towns and cities under all possible varieties of place and circumstance, and yet we have not heard of a single instance in which it was even alleged that the disease was communicated to the attendants and friends.

In "Camp Joe Williams," at Memphis, in 1878, unprotected nurses in the camp hospital were in contact with yellow fever cases for seventy-two days in succession, and yet none of them took the disease. In the same camp, people came out from the infected district in the city with the germs of the disease in their systems, came down with it, were cared for in little army tents by friends and relatives who slept in the same little room, and yet not a person there contracted the disease.

When the epidemic raged on Governor's Island, in New York harbor, five hundred cases of the disease were taken to Quarantine Island down the harbor, and were there attended by unacclimated physicians and nurses, and no one took the disease.

The superintendent of Quarantine Island and his family were also present, and as safe as if in Greenland.

In Gibraltar, in 1854, four thousand people left the infected district, taking their sick with them, and went into camp. There was no spread of the disease from the sick in the camp.

At Jacksonville, during the late epidemic, the nurses that went from the North to the Quarantine Hospital outside the infected city did not contract the disease. Those who went into the city did not escape.

I have yet to see or read of a single case of yellow fever that could be traced to direct contagion as a cause; while innumerable cases of long-continued contact with the sick, where the disease was not contracted, can be given.

The second important fact about yellow fever that, when appreciated, will enable us to control the pestilence is, as I have said, that practically all danger is in the infected district. This fact cannot be made too prominent.

To illustrate, let us study a few data. At Decatur those who came in contact with the sick, but did not remain in the infected district at night, or for many hours at a time, did not contract the disease. At Memphis, in 1878, the physicians who went into the hospital camp outside the city did not get the fever, but of the fifty-four physicians who volunteered to go into the city, fifty-three had the fever and thirty-three of the number died. But here is a still more striking fact, that has, in truth, the completeness of a test-experiment. At "Camp Joe Williams," outside of the limits of the city some miles, there were nine nurses taking care of the yellow-fever cases that developed in the refugee camp. After nursing for a length of time there in safety, and thus thinking themselves proof against the disease, five of the nine nurses determined to go into the city to nurse, as they could there get better wages. The five went into the city, remained a few days, and returned to camp. All five immediately came down with the fever and died. Their companion nurses who nursed them and others, and were, as I have said, in contact with the disease seventy-two days in succession, but kept out of the city, escaped the disease altogether.

Dr. Mitchell estimated that as much as ninety-nine per cent. of all the people who remained in the worst infected district in Memphis had the disease before the epidemic closed. In the less infected districts he thought eighty-six per cent. of the people developed the disease.

Only seven miles away, in camp, the same classes of people suffered not at all from the disease, except those who, in despite of all warnings, ventured down into the city for a day or two.

During the epidemic at Cadiz, Spain, in the year 1800, it is estimated that 57,400 people were in the city during the epidemic, and that 48,500 of them had the fever.

In Xeres, the same year, some 33,000 remained during the epidemic, and there were 30,000 cases of the fever. There were 13,000 deaths. Seville suffered at the same time, and 74,000 of its 80,568 inhabitants had the disease.

In Malaga only 7,000 of its 110,000 inhabitants escaped an attack.

In many of the cities of Mississippi, during the 1878 epidemic, it is thought that not a single white person in the infected districts who had not previously had the fever escaped it.

At Jacksonville, Fla., last season, there was reported to be only about 10,000 people in the city, and there were more than 10,000 cases of the fever reported before the epidemic closed.

Are more facts needed to prove that the infected district is the danger-point in a yellow-fever epidemic, and that all, or nearly all, who remain in it are destined to have the disease, if not protected by a previous attack.

This being the case, we can but see that the prime thing, the only thing to do, is to get the well people out of the "infected district," whether it be large or small, as soon as possible. When this is done the worst epidemic must end in not more than three weeks at the outside.

It is said, and with truth, that many of the citizens of an infected district will refuse to leave their homes to go into the camps that may be provided for them.

This is true, and yet we may ask, What moral right they have to prolong an epidemic for months perhaps, by refusing to adopt the only course that can put an end to it?

Even had the community the right to commit suicide in this manner, they ought not to be permitted to destroy the business and imperil the lives over a large section of country, as they must do, by continuing an epidemic.

We might inquire of the nineteen thousand people who remained in Memphis during the great epidemic: "Had you a moral right to remain there and thus prolong the pestilence until ninety per cent. of your number had been down with fever; until more than five thousand of you had died; until hundreds of devoted attendants and physicians had laid down their lives for you; and a half-million dollars of charitable funds had been expended in your behalf, when, had you gone out to the camps on the hills for a few weeks, the epidemic would have been over, and more than four thousand five hundred lives would have been saved."

The same question might have been put with even greater pertinency to the ten thousand or more who refused to leave Jacksonville for the camps among the sand-hills, where yellow-fever germs cannot germinate.

The money expended by the Relief Association at Jacksonville last season would have sufficed to transport all the inhabitants of that city to watering-places, and boarded them there in luxury until danger from the epidemic was over.

If an individual builds his house over an open sewer, and deliberately and obstinately remains in it while being poisoned, despite all warnings, and then put out his hand for charity to the world, on the plea that he was sick from sewer-gas poisoning, he would not long receive commiseration and assistance. The same rule will sooner or later have to be applied to communities afflicted with yellow-fever epidemics.

This brings me to the methods of controlling these epidemics when once they have started. The infected locality must be depopulated. There is, there can be, no other practical method of putting a stop to the pestilence when once in the community. Depopulation of the "infected district" of all except the sick and their attendants; the removal of the well to military camps; these measures will put a stop to the worst epidemic in three weeks at the outside. In newly made camps the infection cannot obtain a foothold. Yellow-fever germs must have a soil infiltrated with human refuse in order to develop and multiply; such a soil is found in settled towns where drainage and cleanliness has not received particular attention; such a soil you do not find in newly made camps or about new towns. This fact must be impressed upon the public, in the South especially, until it is recognized that the only safe place for the inhabitants of an infected city, such as was Jacksonville and Decatur the last season, is the military camp on the outskirts of the city. To these "camps of refuge" the people must be removed, by force if necessary.

Compulsory depopulation of the infected districts and removal to military camps may seem, at first thought, a harsh, arbitrary, and un-American method of dealing with the danger; but it is, in fact, the kindest and only humane treatment of the trouble. Whenever it has been tried, as at Gibraltar, in 1804, in Guadaloupe, in 1837, and with the United States troops at Pensacola, and at many other places, the epidemic has speedily subsided.

Philadelphia and New York, in the epidemic of 1822, saved thousands of lives by the compulsory depopulation and closing up of the infected districts. Not only is the infected community saved great losses of life and property by these measures, but the surrounding cities are saved from panics, prostration of business, and danger of infection, by the placing the would-be refugees in the camps.

Professor Dowell, who has had a wide experience with yellow fever, says in a striking passage:

"First, all should leave who can. Go quick. Do not fall over one another in going, but be calm; go as gentlemen, not as sheep. Take as little with you as possible. If you cannot go far, go to the nearest point that is high and dry. Do not go back in the daytime, but especially stay away at night. Live in tents, not in houses; and if the disease is brought you will not take it, even by sleeping in the same bed."

The "camp-cure," if I may so call it, is the only practicable remedy for a yellow-fever epidemic when once it is started.

If the foregoing premises be well taken, it at once becomes evident that the United States Government is the only authority that can deal successfully with this pestilence. Prompt and vigorous action at the first outbreak of the disease is essential. How shall this be secured? Evidently we cannot trust to the officials of the community in which the disease may appear. While this trust might not be betrayed in some communities, in others a short-sighted self-interest would lead them to deny the existence of the disease until perchance it was too late to control it. But even if its presence is admitted, in nine cases out of ten the community will have neither the means nor the wisdom to deal successfully with so formidable a danger. The States are not much better prepared to manage this disease. Setting aside the danger of opposition to the State officials by the community in which the epidemic occurs, as at Decatur, the amount of money required, the materials—such as tents, protected nurses, expert physicians, etc.—could not be procured in sufficient quantity to meet the exigencies of an extensive epidemic.

Nor can I see why any State or community should desire to manage by itself an epidemic of this kind. A yellow-fever epidemic is never a local question. It is never even a State question. Every State in the South is damaged by an outbreak, however obscure the community in which it occurs. When all are affected all are interested in having the disease promptly stamped out. Why should the mere sentiment for "State rights" in any Southern State lead it to cry "hands off" to the general Government if it attempt to put down a danger that threatens not a single State, not the South alone, but the whole country as well.

To meet this danger I would suggest:

1. That Congress appropriate one million dollars to be at the disposal of the National Board of Health, or the Marine Hospital Service, for use in epidemics of yellow fever or cholera that may occur in any section of this country.

2. That Congress enact laws empowering its boards to take full charge of any community where the fever may develop, and continue in charge until the epidemic is over, and the danger of infection of surrounding communities is past.

3. These Government boards shall appoint not less than five subordinate boards of yellow-fever experts, to be stationed during the months of June, July, August, and September, one in each of the following cities: Charleston, Atlanta, Montgomery, Jacksonville, and New Orleans.

4. There shall be stored at not less than fifteen of the

leading Southern cities Government supplies of rations, tents, bedding, clothes, and medicines, to be used in the event of an epidemic.

The following general plan of procedure seems to me to be the proper one in case the fever shall appear in any city or village in this country:

1. It should be made the duty of the Local Health Officer of any community in which a suspicious case of fever may appear, to telegraph to the nearest board of Government experts notifying them of the case.

2. On such notification one or more of these experts should proceed at once to the town indicated, and if the suspicious cases prove to be yellow fever they should take steps to prevent the citizens leaving until they have passed at least ten days in the quarantine camp to be at once established. This measure would prevent panics in the neighboring towns.

3. All the material necessary to establish and equip a camp should be ordered and brought on special trains from the nearest depot of Government supplies, and a camp be made just outside of the infected community. To this should be removed all in the infected district except the sick and their attendants, who should be protected nurses and physicians.

4. After ten days in camp those who desire it should be permitted to return to the uninfected parts of the city or to go North; the destitute in camp should be maintained at the Government's expense; the camps should be well guarded and policed; camps for the white and colored should be separate; in short, such measures taken as would make the camps agreeable places of residence for a few days or weeks. There would thus be no necessity for asking charity of the country at large.

5. None should be allowed to re-enter the infected district until all danger of infection has passed.

This district should be fenced in and guarded.

6. Special boards of experts should be continuously stationed in Southern Florida, and if yellow fever becomes endemic there, intercourse between that section and the rest of the country must be closed during the five hot months of the year.

7. All inland quarantines, as well as those on the seaboard, should be under the control of the Government, and should be so managed as to interfere as little as possible with trade, railroad travel, and traffic, especially in sections where the fever does not exist.

So called "shot-gun quarantines," and those established by communities independently, should be discouraged as useless and injurious.

The methods outlined above are to meet the danger when it is once within our border. This is not the place to speak of measures to keep it out of the country, a most desirable end, but one that cannot always be attained, whatever precautions may be taken.

The plans here suggested may seem bold and radical, but will anything less suffice? The old plan of leaving the community attacked to fight the pestilence with only such aid as charity and volunteer help may give, has failed to check the course of the epidemic nearly as often as tried, and now, with the danger increasing year by year, and the magnitude of the interests endangered greatly increased, the country ought not to content itself with methods that have long since proved failures.

"THE TONGUE IN DIAGNOSIS" is the title of a chart devised by Dr. D. C. Benson, of Baltimore, which, as its name implies, is intended to show at a glance the diagnostic points which may be learned by an inspection of the tongue. It is useful in the way of impressing the fact that the condition of the tongue is often an indication of digestive disorder, or even of the general condition of the patient; but the author is rather fanciful in his attempt to draw a map of this organ with the several parts of the digestive and respiratory systems marked off on its surface.

SIGNS OF THE MORIBUND CONDITION.[1]

BY JOHN SHRADY, M.D.,

NEW YORK.

THE tendency in this, as in like discussions, is toward a pathognomonic programme, in which dogmatism is to hold a high rank. Such unmathematical dangers it is well to avoid; conclusions must not be illogically reached, nor should facts be distorted or misinterpreted. Here, if anywhere, the utmost judicial calmness should prevail, for great interests, even with the most humble, are at issue. Is not death the climax of all individual sorrows, a grief which the most assiduous training can barely assuage? There is a recoil, a grand rally in a most desperate fight, and it is no more than fair to presume that the footing up of all the forces summed up under the conventional term of nature, or, if you please, of the constitution, must show a respectable average of importance. If there are forces which collide, there is necessarily a struggle; and if a struggle, a victory or defeat.

The majority of deaths have somewhat of a common complexion, recognizable in a more or less general degree, according to the analytical powers of the observer. One depends upon intuition, which is a kind of unconscious cerebration, while another will weigh evidence, and come to a slower, more correct conclusion. Again, the optimist will consider only the glowing exceptions, and will in every instance content himself with lottery investments, while the pessimist will figure out only gloomy portents. Let us bear in mind that prognosis deals with but two issues—life and death—that between these two it limits all its prophecies, and further, that the bedside friends care to be informed upon two points only—the diagnosis and the prognosis. How often have the presages, garnered as superstitions in the families of the lowly, put to the blush the confident prognosis of the erudite attendant, who has been foiled in his well-meant efforts. Then, again, how rife are the stories of his sombre predictions that have never been verified. May not the explanation abide with remembered successes and forgotten failures? May not coincidences take the color of facts, and the whole matter constitute a tribute to the conceit rather than to the sagacity of the presager? The soothsayer may have merely won a wager upon two bald antagonisms.

Perhaps the present paper may add nothing to the knowledge already in possession of the profession, but sufficient will be the reward if it but enlarges the sphere of study. The axiom that most men care not for details needs only a passing reference; but it is that very attention to the minutiæ which marks the skill of the detective. There are pathological as well as physiological laws, and both are susceptible of intelligent interpretation.

The Hippocratic face has come down to us as a legacy of the ages; it is a description of the moribund condition only in its last stage, and as such is the faithful record of a most accurate observer. It is a graphic summary of phenomena true to nature, to which nothing material may be added so far as physical appeals to the senses are concerned; it is the study of man in the supreme moment of his dissolution, when the temple of his body has already gone into dilapidation. Here, too, are the bold outlines of a strong limner who has left his sketch to be rounded out by other artists. The classical description of this master-mind of medicine, to have been of any great value, should have included the symptoms of the death-approach in the mildest and most creeping phases of its advance. For here time is of value, and deception or ignorance is out of place with him who needs must settle his account hastily but intelligently. Many reasons, therefore, clamor for the expediency of an early recognition of the death-signs, in which are involved such paramount questions of individual, legal, and social impor-

[1] Read before the New York County Medical Association, April 15, 1889.

tance. Besides the rather immaterial desire of the physician to escape censure, which is the lowest view of the question to be considered, there are appeals to the conscience which must be met with candor, for even the haughty Elizabeth of England is reported to have agonizingly offered "millions for an inch of time." But with this simple allusion to the moral aspects of the subject, the importance of which need not be discussed, the enumeration of the signs themselves are naturally in order. As may be inferred from what has already been said, the great philosopher described a condition when all tormenting officiousness must be abandoned, when hope must yield to the mercy of a peaceful departure.

The signs, then, which belong to the antecedent period are only of sufficient importance to be included within the margin of the present paper, and may be said to appear exceedingly early. Of course all those cases of death which occur with suddenness so appalling as to preclude all possibilities of prediction, and which are so gratefully desirable to some minds, come in for no share of the present discussion. They are the prayer of the soldier who prefers to be killed outright rather than suffer from a wound with only a vague chance of recovery. These sudden cases, usually hemorrhagic in the aggregate, and most frequently met with in the lying-in chamber, give, however, some little hope, even when the radial pulse is imperceptible, provided jactitation be absent, always excepting, of course, when the gush of blood is not at the start overwhelming. Cerebral exhaustion explains the tossing about of the patient.

There are many indications—early and dimly foreshadowing in character—such as may belong to the mere adjuncts of individual life, accompanying but not essential. Under this class may be comprised the suppression of the catamenia where there is a diversion in favor of the acknowledged vital functions; such as the late Dr. Willard Parker aptly likened to an effort to save the hull by the sacrifice of the spars. Months may elapse before the catastrophe, but the catastrophe is almost certain to arrive. Colliquative diarrhœa, as showing defective assimilation, along with muscular relaxation and the loss of serum comes on much later, sometimes at the very close of the disease. This, however, requires corroboration by other signs, such as epistaxis and hemorrhagic alvine discharges, which are so frequently observed in critical cases of typhoid fever, and in the purpuric spots of the malignant forms of the exanthems. More important are the ophthalmoscopic revelations of shrunken retinal arteries and a pallid optic disc; but there are some objections on account of the applicability of this test on the score of annoyance, since the death-chamber has an etiquette of its own. An abnormal appetite, styled by the Scotch "the hunger of death," may be regarded as something more than a purely psychical symptom, and may be interpreted as an intuitive, although irrational, desire to overcome that sense of goneness in extreme exhaustion. It might be called the wail of the nutritive system, and typifies a condition rather than a phenomenon. This may be noticed in the last stages of phthisis, low fevers, and in cerebral complications, and usually will prove in the end a false beacon. Optic delusions, as manifested by picking and fumbling of the bedclothes, extreme muscular prostration by the sliding toward the foot of the bed, and irregular spasms of peripheral muscles in subsultus tendinum may all be said to "break the promise to the hope." The dilated, glazed eye and relaxed smile also give no more cheer; but, on the contrary, are only later editions of the same pitiful story. No matter how, death begins at the periphery and ends at the centre; growth shoots forward, decay recedes, as is made obvious in the plant, which withers in the leaf before it shrivels in the stalk.

The dying state can never be arrested; if once begun it must end; therefore, as already seen, it behooves us to recognize it as early as possible. Clearly all unverified prophecies are mistakes in prognosis. The individual who struts the streets, vaunting that years ago he cheated death, never neared the archenemy of his race—he merely sighted but never crossed the line. Watson, in his charming treatise upon "Practice," takes up the simile of the stopped watch and asks what may be the cause. Truly the only way to discuss the phenomenon is from the mechanical stand-point. The heart is the force-pump, whose motor is nervous force—the ultimate origin and essential qualities of which can never be discussed with either wisdom or satisfaction. For the present purpose it is quite sufficient to concede that the heart finds its immediate stimulus in the blood, and that sudden deaths are mainly due to interrupted blood supply. At present heart-failure has become a cant phrase, under cover of which many improbabilities are concealed.

Probably the pulse has been always regarded as the most reliable indicator of approaching disease. The touch probably gave Hippocrates, and after him a long line of followers, the first triumphs in prognosis. To the skilful observer it certainly imparts no little value in the making up of an opinion regarding an issue. An intermittent beat, even though due to the excessive use of tobacco, coffee, etc., the encroachments of age, or the manifestation of the emotions, may well be regarded with apprehension. And yet, such is the uncertainty of our science, a pulse (for instance in the gouty) may intermit for years. Such a condition may only concern the far-off future, but it nevertheless sounds an alarming note, especially when it occurs in the course of a debilitating disease. The writer in more than one instance, as in consumption and cancer, has known it to be a virtual herald a fortnight before the occurrence of death. It may even disappear entirely during an interval of indefinite continuance, but it certainly means something. In all dubious cases the sphygmograph, provided the mechanism be sufficiently delicate, or its tracings rightly interpreted, might prove of inestimable prognostic value. Aside from this aid which so captures the eye, many also have an intuitive discrimination of the pulse's force and volume who are incapable of analyzing successive waves of sound. To most who have not the musical gift, sounds are a jargon rather than a language, and to such as these the touch is really of more value than the stethoscope. Let it be remembered that the pulse with our ancestors imparted a deal of knowledge, long before the advent of the clinical thermometer; with them the tactus eruditus took the place of all other devices.

After the intermittent pulse, which, as already asserted, appears so early in the stage, there are many points quite apparent to the senses of the observer, such as the ashy tint of the countenance, the purple-hued nails, the distinctive white lines around the orbicularis oris muscle in serious forms of scarlatina, as taught by Trousseau, the whispering voice, the pleading look, and the grunting respiration. All of these are expressions of a hindered circulation or shock, and usually are not indicative of pain. These minor variable conditions give at times many illusory hopes of an improvemement, although in the main the symptoms are halts upon the steps of the terrace, the slope being still downward. Subsultus tendinum, hiccough, and convulsions, which appear later, also belong to the phenomenal manifestations of the nervous system, and may be regarded as peculiar disturbances.

Left unilateral dropsy, beginning in the foot, is a very valuable sign of the gradually approaching end, as showing that the circulation is beginning to falter in its work. This sign, which may be classed as a kind of folk-lore, claiming a long line of descent, is much commented upon by relatives and friends. Conjoined with this may be noticed a coldness of the ears, tip of the nose, and the malar regions, to be followed much later on by the same conditions in the patellar surfaces. These may come and go at longer or shorter intervals—perhaps weeks may elapse—but they are ominous of evil.

Among the unclassified symptoms indirectly referable

to the brain, in the general sense of the aggregation of nervous centres, temperature must be considered. With the specially dangerous temperature of 105° F., particularly if long maintained, an unfavorable prognosis should be the rule, with little, if any, qualification. This degree is not very uncommon in a paroxysm of intermittent fever; but the duration is short and seems to be of not much significance as regards marked constitutional disturbances. In very truth, when it manifests itself as a short, sharp invasion, it should afford more consolation than the slow, insidious, and only slightly curved ranges. "A sustained pyrexia," says Fothergill, "melts down the body-tissues and endangers life from the accumulation of the products of nitrogenized waste in the blood." Caution should be exerted against slovenly observations confined to the surfaces of the body, as, for example, when the writer unexpectedly found a rectal temperature of 108° F., with palpably cold extremities, in a case of malignant scarlet fever which ended in death, during the ante-eruptive stage, but a few hours after seizure. The temperature in this instance started with a record of 102° F., at 7 A.M., and death took place at 10 P.M. The occurrence of scarlatina in other members of the family within a week afterward aided in the diagnosis. If temperature represents molecular changes, surely here was an instance of intensity in disintegration, or as Williams, in accordance with an older view, puts it in his "Principles of Medicine," here was "the premature triumph of dead over vital chemistry." The explanation of phenomenal ranges such as these must be looked for somewhere along the line of the ganglionic system of nerves, which presides over the functions of nutrition, secretion, excretion, etc., a system incapable of independent study, since it cannot be isolated. There are, besides, conditions of abnormally low temperature met with in the subject which escape observation, particularly in shock, because they are not submitted to the thermometer. Nor, indeed, have they been sufficiently studied to form a system in view of the evidences furnished by other concomitants. A temperature below 95° F. is usually quoted as being very serious.

Coma, which may be regarded as a form of asphyxiation dependent upon some deleterious force or agency affecting the nervous system, is to be regarded among the surest signs of approaching death. This phenomenon may, primarily, arise from acute pulmonary disease, or, secondarily, from deficient or impure air. Besides the stupor, it may be outwardly manifested by alar or abdominal respiration, or, to express it more tersely, the supplementary muscles of breathing drawing the bony framework of the chest upward, may be brought into requisition for extra work. The blood amenable to toxic influences affects the brain, and through it eventually paralyzes the respiratory organs. The onset of the symptoms may be so insidious as to escape notice, especially when the actual count of breaths is omitted. Here, in passing, it may be noted that when the respirations are thrice the normal, and continuous, an unfavorable prognosis should be the rule. Perhaps the only exception, and that a partial one, is to be found in the case of uræmic asthma, either with or without pulmonary œdema; but even this condition does not admit of many repetitions. Fortunately even here the brief duration is in its favor, notwithstanding the suspicion that the function of the pneumogastric nerve is invaded; to put it metaphorically, the enemy is on the skirmish line.

In the absence of pain but very few have a conviction of impending death, unless there be a sudden cessation, when the popular notion of so-called mortification plays the part of alarmist. This immunity readily explains the hopefulness of the consumptive, and, in part, the ecstasy of those whose ganglionic system has suffered a paresis by reason of some extensive mutilation. Hence the difficulty in such cases of obtaining ante-mortem statements, in which, as an earnest of truthfulness, the law requires a clear mind, a sense of responsibility, a belief in impending dissolution, and that innate sense of justice that the innocent be not wantonly or maliciously accused. Many victims of mortal injuries, in these official interviews, cannot be induced to believe that there is even a remote probability of death, so perfect is the euthanasia; they seem willing to make the impartial, candid statement but not an admission of the precarious tenure of their life. Thus the law admits a doubt of absolute sincerity and accepts only clews for corroboration, when evidence, presumably overwhelming, should be given its full face-value.

The unrhythmical respiration, named the Cheyne-Stokes in honor of its co-describers, may also, in common with uræmic asthma, manifest itself at odd intervals, as also the exhilaration of uræmic poisoning, which the late Alonzo Clark was wont to describe as it occurred under his observation in the Bellevue wards. He said that he regarded the pranks and jollity of the subjects as a sure precursor of an early death; he maintained that this was a stage antecedent to coma, and bore about the same relation the one to the other that the hilarity of drunkenness did to its stupor—that it was merely the edge of the coming storm.

Of all the physical signs, the up-and-down movement of the pomum Adami, as temporarily seen in the act of swallowing, appears very early in certain forms of the dissolutive stage, usually at the period of tracheal râles; in phthisis it may precede the catastrophe even a fortnight or longer; of course, in pneumonia, its invasion, so to speak, is more pronounced, and its duration immeasurably more brief. The writer has observed it so frequently that he has come to regard his suspicions as convictions. This movement may be the measure of an overwhelming generation of carbonic-acid gas, or an insufficient supply of oxygen. It is very marked in pulmonary complications, and when appearing in diphtheritic croup neither tracheotomy nor intubation is available; this statement should have the force of a rule. Although hardly able, from infrequency of opportunities, to generalize, yet the writer has mentally predicted the issue of certain operations on this spectral sign alone. He well remembers a case in which, during narcosis by ether, respiration was maintained by tracheotomy, and the patient died, notwithstanding all the favorable surroundings when this warning was conspicuous and constant throughout. He does not pretend to say that the surgical interference was an etiological factor, but simply unnecessary, as proven by the sequel. Still, in these cases the pressure brought to bear in favor of a trial for salvation may be irresistible in its pleadings; so then, in similar contingencies, let there be no assurances but rather a guarding with discounted hopes. The explanation of the phenomenon in question may be said to be resident in the par vagum, made manifest by a paralysis of its inferior laryngeal branch, although some aver that muscular effort alone may furnish a ready interpretation. It is a fact demonstrated by vivisectionists that when the pneumogastric on both sides is divided there is an increased rapidity and difficulty of inspiration. The animal becomes quiet soon after the operation, without evidence of suffering, the character of the inspiration being long, slow, easy, and silent, while the expiration is sudden. The writer has fortunately at hand the notes of an autopsy of a dog upon whom the late Professor Dalton had ligated both pneumogastrics, the duration of life having been exactly two days. The death, as given in the verbatim report, was brought about in the following manner. The glottis was paralyzed; the inspiration accordingly became labored, and sucking. The stimulus to respiration was also less, the carbonic acid not being as irritating as before the division. The next step was a stagnation in the pulmonary capillaries, owing to the fact that the glottis could not take in sufficient air. The circulation being interfered with the blood began to block up; the respiration, being less and less, constituted a condition of imperfect arterialization, and carbonic acid, being a narcotic poison, produced coma. With this explanation, which in the notes is still further pursued, touching as it

does the act of swallowing and the arrest of the peristaltic action of the intestines, the significance of this patent manifestation may be readily divined. Our colleague, Dr. F. A. Thomas, an ex-Surgeon of the Police, who had become much interested in the prognostic value of this sign, was wont to apply it as a test for those cases which bring so much opprobrium upon medical practitioners in public life; to wit, the ability to decide between drunkenness and compression of the brain by blood-clot or fracture. He escaped much future embarrassment by his conviction that this paralysis of the glottis is invariably absent in alcoholic intoxication and present in the moribund condition; in other words, he accepted the gravity of the case at once if he noticed this up-and-down movement of the pomum Adami, and took good care that the individual arrested for being drunk had some better accommodations than a cell, the omniscient policeman to the contrary notwithstanding.

The conclusions of the writer are:

1. That in general the signs of death that are the most trustworthy appeal to the eye.

2. That among these the respiratory function holds the first rank, both in cases of coma and asthenia, more noticeably when the two modes of death are blended.

3. That the death by coma represents, in duration, the longest period.

4. That the most valuable sign of inevitable dissolution is the up-and-down movement of the pomum Adami, always providing that it be persistent.

5. That temperature-changes deserve recognition, particularly when the curves are sharp, high, and continuous, or when they are below the normal.

6. That an intermittent pulse is an early sign of death, especially when not due to any disturbed action of the nervous system. The qualification necessary to save this statement from being absolute lies in the fact that occasionally individuals are found who maintain this peculiarity through a long, healthful life.

7. That deaths from syncope are too sudden to allow of much observation or study.

"SUSPENSION" IN THE TREATMENT OF LOCOMOTOR ATAXIA.

By EDWARD WAITZFELDER, M.D.,

NEUROLOGIST TO THE RANDALL'S ISLAND HOSPITAL, NEW YORK.

My first induction into the suspension treatment of locomotor ataxia was through the columns of the *New York Herald*. Rapidly following this appeared articles in The Medical Record and *New York Medical Journal*, *Philadelphia News*, *Times*, *and Register*, *Journal of the American Medical Association*, etc. The impression I gained from reading these articles was that the treatment was empirical, it being illogical, untheoretical, and unscientific; as any treatment must be that claims to decidedly improve, if not cure, a condition that is the result of a connective-tissue degenerative inflammation in nerve-tissue.

In locomotor ataxia the relation between cause and effect is perhaps better marked than in any other of the nervous diseases. As the nerve-cells are encroached on by the proliferated fibrin-cells and leucocytes, so do the hyperæsthesia and paræsthesia manifest themselves. After the organization of these elements into connective tissue (which here, as everywhere, shows its inherent property of contraction) anæsthesia becomes more and more marked as the nerve-cell becomes more and more compressed, until death of the nerve-cell and complete anæsthesia results. But the process does not stop here, for the contraction still persists, and finally the nerve-cell is completely obliterated.

It has been stated that a cure has resulted in well-marked cases of ataxia after the suspension treatment has been continued for a long time. Now, while we know that regeneration of normal tissue may take place in bone, muscle, skin, etc., I have never seen any report of such regeneration taking place in nervous tissue; and I think it is a rule to which there is no exception, that when death of a nerve-cell has taken place regeneration is impossible and the function of the part supplied by that cell is destroyed forever. I have now under observation a case of diffuse peripheral neuritis (post-diphtheritic) in which there has been an apparent complete recovery, but close and careful examination shows there is still a paresis of some of the small muscles, which beyond doubt will be permanent.

Impressed as I was with the idea that our present resources for the treatment of locomotor ataxia were of no value, even in relieving the distressing symptoms of the disease, I began the suspension treatment in the nervous ward of the Randall's Island Hospital with but little hope of benefit and more from a sense of duty to the unfortunate patients than from any expectation of doing good. The patients were all males, Sayre's apparatus being used. The treatment was conducted under the personal observation of the house physician, Dr. McCready, to whom I wish to acknowledge my thanks for the accompanying histories.

In consequence of a mistake of mine the early part of the treatment was carried out by suspending the patients three times a day for three minutes each time, so that the first fifteen suspensions in all the cases occupied a period of but five days. In two of the cases most marked and rapid improvement took place at the beginning of treatment. After this, the treatment was as follows: Commencing with half-minute suspensions on alternate days, the time was increased one-half minute each time until three minutes was reached (sixth suspension); after this the patient was suspended for three minutes every second day. The patient was raised just far enough to let the tips of the toes touch the ground. In some of the cases the loops were put under the axilla; in others they were left off.

Case I.—M. O'S——, aged thirty-nine. History (of ataxia) for three years. Fulgurating pains; cramps in feet and legs; diplopia; incontinence of urine, etc. After fifteen suspensions: Incontinence of urine less marked; can now hold urine a short time. No pains since treatment began. Gait improved. Patient says he feels stronger. After twenty-four suspensions, can hold urine now for ten minutes. Has had no "pains" or cramps in legs and feet since treatment began. Gait very much improved. Ataxia in walking markedly diminished. Can walk almost in a straight line with eyes closed.

Case II.—Aged thirty-eight. Cerebellar hemorrhage (?). History for seven years. This patient was placed under suspension treatment by mistake for a case of ataxia. After twenty-four suspensions gives general subjective improvement, says he feels stronger in his legs, and can walk better, but as he is willing to agree to anything his statements are of little value. No objective improvement.

Case III.—J. D——, aged sixty-three. History for eight years. Fulgurating pains very severe and frequent; girdle sensation well marked and painful; anæsthesia of feet and legs; diplopia; "Argyle-Robertson" pupil; ataxic gait very characteristic. Cannot stand with eyes closed, marked straining at urination, etc. After fifteen suspensions can stand for short time when eyes are closed; gait very much improved; can now walk without a cane; numbness of feet diminished. The feet, which were always cold before, are now warm. Anæsthesia of feet less marked. Can pass urine easier than before. No improvement in pains after twenty-four suspensions. Pains unaffected. Patient thinks they are more frequent and severe than before treatment. Gait very much improved; formerly walked with a marked ataxia of feet, bringing down the heel with a severe shock. Now the walk is very slightly characteristic and the "stamp" of the heel very little and would

hardly be noticed. There is very little inco-ordination of the feet, and the entire appearance of the patient when walking is changed for the better. Urination less difficult; patient says, "Can pass urine more freely and with less effort." For the past two or three years has always complained of cold and dry feet, his feet never being even moist in the warmest weather; since the commencement of the treatment his feet have been warm, and for the past two weeks have perspired naturally. Subjective increase of strength in lower extremities and back; can walk a longer distance now than before. Cramps in legs, which were frequent before, have entirely left him.

CASE IV.—Aged fifty-six. History for nine years. Shooting pains and inco-ordination of lower extremities; girdle feeling. Absent reflexes. Romberg symptom, diplopia, ptosis, difficulty in urination, etc. After fifteen suspensions, much improved in general condition, walks better; legs feel stronger after twenty-five suspensions. Before treatment had fulgurating pains and cramps in feet and legs almost every night, now has cramps in legs only about once in ten days and they are not so severe or of as long duration. Has had no pains at all since suspension was commenced. Urinates with less difficulty, and bladder less irritable. Used to have to empty the bladder five or six times every night, now has to urinate two or three times during the night. Gait much improved, but little "stamp" to the heel. "Can walk a mile now with as little fatigue as a quarter of a mile before."

CASE V.—A. C——, aged fifty one. History for three years. Fulgurating pains, inco-ordination, gastric crises, ataxic gait, girdle sensation, diplopia, etc.

Until four days before suspension was commenced patient was confined to bed for over eight months on account of extreme ataxia of feet and legs. Whenever he would attempt to walk his legs would move about in the most irrregular way, and as he could not place his feet on the ground with any degree of certainty at all he entirely gave up walking. After sixteen suspensions his gait is fairly good, though it still shows some inco-ordination; he can follow a straight line for a short distance, can start walking and stop abruptly without much staggering, can turn about suddenly ("right-about-face") with only a little wavering. Has not been in bed in the day-time since treatment was commenced. Diplopia almost gone; subjective increase of strength in lower extremities since commencement of suspension.

CASE VI.—C. B——, aged fifty-three. History for five years. Fulgurating pains; ataxia of legs; weakness of legs and back, and general disinclination to move about; patient used to sit in the ward all day, very seldom moving from his chair; said he was not able to walk. After fifteen suspensions: So much improved that he insisted on having his discharge, saying he was entirely free from pain, and could walk as well as he ever could. The improvement was marked from the first suspension. In this case the suspensions were made for three minutes at a time, three times daily, for five days. I did not see this patient at the time of his discharge, but Dr. McCready, the house physician, states that his gait was entirely normal and his general condition very much improved.

That there is a direct relation between the effect and cause in these cases there can be no doubt. In all the cases, for years there had been no change at all, or a gradual increase in the severity of the symptoms. All plans of treatment had been followed and abandoned. While under the suspension treatment practically no medicine was used, only one or two cases taking an iron tonic (ward mixture). Everyone of the patients said he was better than before treatment. At first I thought this might be due to psychic influences and the result of suggestion, as there was a free interchange of opinion among the patients regarding the treatment, and Case II. points strongly in that direction. But I am now confident that this is not the case, and that there had been a direct impression produced on the spinal cord, but in what way I am as yet undecided. It is hardly reasonable to suppose that the cord itself was stretched, for it floats so freely in the spinal canal that the counter-extension of the weight of the body is not sufficient to produce that result without the greatest pain. It is more likely that the traction exerted on the spinal nerves in some way brings about a change in the circulation and nutrition of the cord, and the amelioration of the symptoms is due to a lessening of the vascular supply of the cord and its membranes. How the result is brought about I am unable to say, but that there has been not only a subjective improvement (which in itself is of great importance), but also an objective one, the above cases fully demonstrate.

Progress of Medical Science.

HYDROXYLAMINE IN SKIN DISEASES—Hydroxylamine is used in different skin affections as a substitute for chrysarobin and pyrogallic acid. Similar to those, it has highly reducing properties when brought into contact with O-carriers. Its medicinal use was first proposed by Professor Binz, and first practically applied by P. T. Eichhoff, while it is known as a chemical substance ever since 1865, when Lössen obtained it by reducing nitric ether of methylene with granulated tin. Hydroxylamine is a strongly alkaline substance, which, combined with acids, forms well-crystallized salts. In a free state it is only known as watery solution. Its chemical formula is

$$N\begin{cases} OH. \\ H. \\ H. \end{cases}$$

which shows that it derives from ammonia, in which one atom of hydrogen is replaced by hydroxyl.

Hydroxylamini hydrochloras, or

$$N\begin{cases} OH.\ HCl. \\ H. \\ H. \end{cases}$$

is obtained by adding hydrochloric acid to the solution in water. It consists of colorless hygroscopic crystals, soluble in water, alcohol, or glycerine. The solutions turn blue litmus paper red, but leave Congo paper unaffected.

Eichhoff used the following formula:

℞. Hydroxylamini hydrochlor..... gr. ij.
Spirit vini,
Glycerin..... .....āā ʒ ij.
S.: For external use.

After preparatory washing of the diseased parts of the skin with soft soap, this solution was applied from three to five times a day. It has been proposed to use ointment as a base, but the formula above is to be preferred, as the alcoholic solution penetrates the skin much more rapidly than ointments. The author has tried hydroxylamine in the following skin diseases: Ringworm, sycosis parasitaria, and lupus vulgaris. Especially with lupus, his results have been excellent. He furthermore thinks cases of psoriasis and chronic parasitic eczema suitable for the hydroxylamine treatment. He strongly advises further trials and experimenting with the new remedy, which has the advantage of combining cheapness with usefulness. Not only by Eichhoff, but also in the Vienna clinics, an ointment of the following composition is employed:

℞. Hydroxylam. hydrochlor..... gr. ij.-viij.
Lanolini..... ʒ iv.
Ol. olivæ..... ʒ ss.

—*The Provincial Medical Journal.*

CONGENITAL CEREBRAL SYPHILIS.—Dr. Angel Money recently exhibited before the London Pathological Society specimens from a case of chronic syphilitic meningitis, arteritis, cerebral atrophy, and sclerosis in a boy aged four. He was first seen at the age of eleven months, suffering from hydrocephalus. The skull was natiform, the root of the nose depressed, the spleen enlarged, and there were

signs of disseminated choroiditis. Syphilitic taint was discovered in every member of the family. The boy improved and seemed to be almost well until, on August 18, 1888, left spastic hemiplegia developed. On October 11th, he lost his speech and developed right spastic hemiplegia, and on the 19th he died. At the necropsy, the brain and dura mater were found to be adherent everywhere, but the adhesions could be separated. The arteries were much diseased, as was also the brain-substance. The atrophy and sclerosis were most marked in regions supplied by the diseased arteries. The dura mater was four lines thick in the temporal regions, and resembled a fibroma in structure. The ependyma was granular in appearance, due to the formations of granulations composed of small, round nuclei, and the structure was of considerable density. Dr. Money also exhibited the brain of a microcephalic child, showing atrophy and sclerosis of the left hemisphere without disease of the arteries or membranes, but yet of syphilitic origin. The child could not stand, or sit, or talk, and all the limbs were weak and spastic, but the left arm least so. Death occurred at the age of sixteen months, and the brain weighed fourteen ounces.

Sculptor's Chisels in Osteotomy.—Professor König, of Göttingen, states that in performing osteotomy he has for some years used chisels, from one inch and a fourth to two inches in breadth, and has found that he can thus divide the bone very speedily and without the exercise of much force. Three cases are reported to show the advantages of these instruments. One is a case of anchylosis of the knee-joint treated by division of the articular extremity of the femur, another of division of the shaft of the femur for shortening and distortion after fracture of this bone, and the third a case of division of the femur after Macewen's method for genu valgum. An incision having been made at the usual situation, the soft parts were separated by an elevator from the anterior and posterior surfaces of the bone, and the sides of the wound separated so as to allow the introduction of a chisel broad enough to divide at once the whole thickness of the femur. The chisel was not applied at right angles to the long axis of the bone, but obliquely, so as to be driven obliquely from below and inward, upward and outward. An osteotomy thus performed is usually completed in a few minutes, except in cases of adult subjects, in which a longer time is required.—*Centralblatt für Chirurgie.*

Prolapse of the Placenta, without Placenta Prævia.—Münchmeyer has reported two cases of prolapse of a normally attached placenta in which the placenta was born before the child. The first was a multipara with a flat, rachitic pelvis; the fœtus was in head presentation. Labor proceeded without hemorrhage until the os was dilated; the head failed to descend; the placenta was not perceived on examination. The placenta suddenly presented, after several strong pains, in the vagina by its fœtal surface. The patient was immediately anæsthetized, the vagina disinfected, and the hand introduced and the placenta expelled. The membranes had ruptured at the border of the placenta, they were otherwise intact. Neither fresh nor previously coagulated blood was found on the placenta. The cord was cut, and it was found that the feet of the fœtus lay beside the head. Extraction by the feet was attempted, but the size of the fœtus and the impaction of the arms rendered it impossible, and embryotomy and craniotomy and delivery of the head with the cranioclast were performed. The mother suffered from parametritis with abscess, but recovered. The second case was twin pregnancy in a multipara; after a prolonged first stage a female child was born living; there was no hemorrhage, nor did examination reveal a presentation or prolapse of the placenta. The cord was short (between twelve and thirteen inches long) but was not ruptured. Examination revealed a placenta presenting by its fœtal aspect which belonged to the second twin. The expulsion of the child (stillborn) and placenta followed; the placenta of the first twin was then removed. The two placentæ had been slightly adherent at the chorionic surface; both were *placentæ marginatæ*. The mother recovered without complications. Münchmeyer has no explanation for the prolapse of the placenta in these cases; he mentions the following diagnostic points between prolapse of the placenta in placenta prævia and prolapse when the placenta is not prævia. Prolapse of the placenta when not prævia gives no sign or symptom for diagnosis except sudden failure of fœtal heart sounds during labor; placenta prævia and prolapse are diagnosticated by hemorrhage; in placenta prævia the fœtus often perishes during pregnancy; in prolapse when not placenta prævia fœtal death occurs at the moment of birth; when a normally implanted placenta prolapses it presents by the fœtal surface; placenta prævia presents by the maternal surface; the danger for the mother from septic infection is equally great; from hemorrhage, great in placenta prævia only; the prognosis for the child is equally grave in both cases.—*The American Journal of the Medical Sciences.*

Atrophy of the Gastric Mucous Membrane.—Dr. Meyer has found this condition in a considerable number of stomachs, the atrophy being complete in four cases and progressing in the others. Etiologically, the atrophy arises from a chronic catarrh, which is either primary or secondary to a malignant growth or to toxic gastritis (*The American Journal of the Medical Sciences*). The process may be one of two kinds. First, it may be of a degenerative nature, consisting of an infiltration of round cells, chiefly from the surface, so that the glands are forced to lie obliquely or even horizontally, and are, finally, partially obliterated and replaced by a formation of cysts, with only here and there a remnant of glandular structure. The *muscularis mucosæ* is thickened, and connective tissue projections from it extend toward the mucous surface. Secondly, the process may be of the character of a formative irritation of the intraglandular tissue. In this the naturally scanty connective tissue grows thicker, strangles the glands, leaves a net-work with large meshes, and causes a disappearance of the *muscularis mucosæ*. These two processes, the parenchymatous and the cirrhotic, are often commingled. The author suggests the term "phthisis ventricula," on the ground that the other names applied are unfitting. The gastric wall may be of normal thickness, thinner than it should be, or greatly thickened. The author reports a case in which this last condition obtained. The process begins, as stated, usually on the free surface of the mucous membrane, leads to the formation of cysts, and, finally, to a broad band of connective tissue. All traces of the glands finally disappear. Sex appears to have little influence in its production, but it is most apt to develop in the latter years of life. Carcinoma, even in distant parts of the body, plays an important *rôle* in its etiology. The duration of the disease appears to be between nine months and two years, as nearly as can be determined. The symptoms, though not constant, are dilatation of the stomach, disappearance of the natural secretion and of mucus, diminution of the gastric movements, cardialgia. All these symptoms attend chronic gastritis, carcinoma, and neuroses. The diagnosis is often impossible, but an important symptom is the good general condition and the absence of emaciation, which indicates more than an outward relation to progressive pernicious anæmia, especially when digestive disturbances attend the latter affection. The prognosis is unfavorable, and therapeutics can offer little, though lavage with hydrochloric acid and arsenic may be tried. In view of what has been said, the author deems it important—1, that all patients with carcinoma of any organ, and who present any symptoms of pernicious anæmia, have the functions of their stomach tested; 2, that after death the organ be histologically investigated; 3, that the condition of the vagus, sympathetic, and Auerbach's and Meissner's plexus be studied.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, June 8, 1889.

THE CAUSES OF APPARENT DEATH.

To the lay mind the state known as catalepsy is probably oftenest thought of as the cause of apparent death; and most of the old-wives' tales about burying people alive are connected with a history of a trance or cataleptic state. As a matter of fact, however, catalepsy is extremely rare, and a cataleptic state in anywise simulating death is rarer still.

M. Brouardel, in a recent discourse (*Gazette des Hôpitaux*, No. 55, 1889), has gone over most of the various causes which practically do sometimes cause conditions simulating real death. First among these naturally comes the condition of asphyxia, so often met with in the newborn. Here life may apparently be extinct for one, two, three, or even four hours. It is claimed that the heart may cease to beat for a time and yet that life may be restored. We must hold it very doubtful, however, whether the heart ever renews its action after it has once entirely ceased.

Hysterical patients sometimes pass into a state of trance or catalepsy, in which there is a very great lowering of all the vital functions—a kind of human hibernation. But these patients always show some signs of vitality to even a superficial examination.

Sudden heart-failure with syncope, from various causes, is held to be the most frequent cause of simulated death. Brouardel cites the case of an individual who had been condemned to death, and who was hung by the neck for twenty-five minutes. He was taken down, carried to a dissecting room, where, an hour later, on opening his thorax, his heart was found to be beating. Hoffmann reports another case of this kind.

In the algid stages of cholera and some other infectious fevers a condition resembling death sometimes occurs. It has been shown that certain infections develop ptomaïnes which have a powerful anæsthetic influence upon the organism.

Exposure to excessive cold produces a drowsiness, and finally a coma, which resembles death, and which, in fact, usually ends fatally. So, too, immersion in water may apparently extinguish life. Yet resuscitation occasionally occurs, even after more than an hour. M. Sestier reports seventeen cases of "fulguration," or strokes by lightning, in which the patients remained in a state of apparent death for a long time. In the same way violent falls, concussions, blows, and gunshot wounds may, by causing cerebral concussion, apparently, as well as really, extinguish life.

Partial and non-fatal asphyxiation may be caused by being buried in the earth. It is claimed that in certain cases individuals have been buried for two or three days and still restored to life, but doubtless the earth was light above them.

Carbonic oxide, alcohol, and anæsthetics all may produce respiratory and partial heart-failure, with apparent death. M. Laborde has reported the case of a drunkard who was so poisoned by alcohol that the temperature sank to 76° F. in the rectum, and Bourneville cites a similar case. Both persons recovered.

The tests for death in all these cases are well known, and most of them easily applied. To the eye of the physician the physiognomy is generally enough. The entire and continuous cessation of respiration, of the heart-beat, and of the blood-flow is usually sufficient to confirm the physician in his opinion of the case.

THE PREVALENCE OF PROSTITUTION AND SYPHILIS IN THE UNITED STATES.

A RECENT work by Dr. L. Reuss, briefly reviewed elsewhere, on "Prostitution from a Sanitary and Administrative Point of View," contains a chapter on syphilis and prostitution in the United States which calls for some attention and criticism.

Dr. Reuss takes the stand held by many Continental physicians, that prostitution should be regulated by the State both for sanitary and moral reasons. And he cites the frightful moral and physical condition of this country as an illustration and argument.

There are, he says, three hundred and sixty-eight thousand prostitutes in this country. In New York the number is between thirteen and fifteen thousand; in Philadelphia it is still greater. In each of these two cities there are about fifty thousand syphilitics. In the Marine Hospital service one man in every five contracts syphilis annually; in the navy, one in every twenty. We are told, finally, that venereal diseases form the *chief remunerative source* of practice to American physicians!

The figures and statements thus made will certainly astonish American readers; but it will require only a brief glance at Dr. Reuss' own work to show that his presentation of our case is a ridiculously distorted and incorrect one.

Take, first, the question of the number of prostitutes in the United States as compared with Europe. It would be a small estimate to place the number of prostitutes in Paris at twenty to twenty-five thousand. The lowest estimates are fifteen thousand, the highest forty-five thousand.

In Bordeaux, with 250,000 inhabitants, there are estimated to be 6,000 prostitutes, or twice the number relatively to that of this city.

In Marseilles the population is 362,000; the estimated number of prostitutes, 8,400.

In Vienna the population is 1,169,000; the prostitutes about thirty thousand. In London, with a population of 5,000,000, the prostitutes number about one hundred thousand.

In Berlin, a city of about the size of New York, the prostitutes number about thirty thousand, and the number of syphilitics among adult males ranges from two to four per cent.

These figures all go to show that, if anything, the number of prostitutes is relatively smaller in this country than in Europe. The figures would be still lower if it were not for the pernicious influence of the horde of syphilized and degraded immigrants with which our country has been flooded in recent years. These people not only bring over diseased bodies, but establish and propagate a low grade of morals, acquired in Europe.

Such facts, however, have no bearing on the alleged efficacy of governmental regulation in lessening the prevalence of prostitution or the spread of syphilis. In fact, the figures collected by Dr. Reuss do little more than prove that the attempts of the State to repress the sexual instincts are utter failures.

The spectacle of a Parisian, however, lamenting the immoralities of the Americans is most unique and picturesque.

The fact is that syphilis in many, if not all, civilized countries is in the position of an epidemic in the stage of decline. It is not so malignant and not so infective as it used to be; and in studying the influence of State regulations and sanitary measures upon it, this fact must be borne in mind. Probably in France, the home and godfather of the disease, and even in Paris, where the world, according to Ricord, revolves around the vagina, syphilis is also decreasing in virulence, although the frequency of the hard chancre, as compared with the soft, is said to be much greater than in other countries. Paris is a city with some regulation of prostitution, but with a fecundity in hard chancres that makes it a dangerous resort for the libertine.

TEACHERS' LARYNGITIS.

In a pamphlet entitled "Board School Laryngitis," Dr. George Macdonald, of London, calls attention to a peculiar form of laryngeal inflammation which he has observed in teachers of the Board or Public Schools.

It is essentially an aggravated form of chronic congestion of the laryngeal mucous membrane. It results from the continual strain put upon the voice by persons who are overworked, and whose work is carried on in ill ventilated, noisy school-rooms. Of local causes the primary one is said to be faulty vocalization. The teacher thinks only of making herself heard, and pays little attention to the quality of the voice as long as it is audible. Another local condition is the constant inhalation of chalk dust, which not only irritates the throat, but causes a chronic rhinitis.

In the early stage of the trouble the appearances are simply those of ordinary chronic laryngitis, but in cases of a year's duration or more, one of two conditions is seen:

1. That where varicose veins on the upper surface of the cords form the prominent objective feature.

2. That where various thickenings of the margins of the cords afford the distinctive characteristic.

These two conditions—the varicose and the hypertrophic—are very rarely associated. The laryngeal appearances are carefully described by Dr. Macdonald.

The treatment of the varicose form consists, first, in allaying the inflammatory condition by sprays, inhalations, or local applications of stimulant, sedative, or astringent mixtures, according to the degree of disturbance. The varicosities are then treated by the electric cautery.

In the hypertrophic form one finds usually small benign papillomata such as have been described sometimes as singers' nodules. But Macdonald believes them to be far more constant and characteristic of untrained voice-users. The treatment of these, after subduing the inflammatory condition if it be present, is to remove the growths by means of Mackenzie's cutting laryngeal forceps.

Perhaps the most important suggestion made by our author is in the line of preventive treatment. All teachers, he says, should undergo a course of training in the science of teaching, and should also be drilled in the art of voice-production, not only in singing, but even more in speaking. They should be taught to breathe so that their chest-walls do all the heavy work; while their vocal cords should effect no more than the mere production of sound, the mouth and lips bearing all the onus of producing articulate speech. And herein lies the whole secret of practical elocution. At present the average speaker, whether member of Parliament, clergyman, or schoolmistress, attempts to enforce attention by screaming with the vocal cords, instead of speaking with the mouth and lips. Greater attention should be paid also to the ventilation of schools, and the size of the classes.

We are told that the number of pupils in the classes of our New York public schools is less than it is in most European countries, and Dr. Fayette Smith states that throat troubles are almost unknown among our teachers. It is gratifying to learn also that throat affections are far less numerous among American clergymen, because, as we are told, a scientific training in voice-use is made part of their education. The nasal twang of American speech is perhaps less charming to the ear, but it is a more scientific and rational mode of vocalization than are the throaty intonations of Englishmen. We may be thankful that nature thus has her compensations.

THE INTERNAL USE OF CHLOROFORM.

Chloroform has long been used internally as a symptomatic remedy in flatulence, diarrhœa, neuralgic pains, and cough. It is a substance which is quickly absorbed by the stomach and as quickly passes out of the system by the lungs, skin, and kidneys. Its specific use for serious maladies has rarely been attempted.

There have, however, lately appeared several articles claiming for this drug somewhat remarkable powers. Dr. Clemens, to whose therapeutical observations not much weight can be attached, insists that it is a most valuable remedy in the treatment of acute pneumonia and of acute rheumatism. In these diseases he gives chloroform both by the mouth and by inhalation.

Dr. Stepp (*Münch. med. Woch.*, No. 8, 1889) was led, by the experiments of Salkowski on the disinfecting power of chloroform water, to try its effects in acute pharyngitis, diphtheria, whooping-cough, croupous pneumonia, and typhoid fever. Negative results were obtained in diphtheritic and in tubercular cases, although locally, as a gargle, chloroform water is very useful. In croupous pneumonia the results were satisfactory, and confirmed somewhat the claims of Clemens. Dr. Stepp particularly insists, however, upon the value of chloroform water in typhoid fever. The Berlin correspondent of the *Medical Age* writes regarding this point:

"The mode of application was fifteen drops of chloroform dissolved in five ounces of water, given in equal parts daily. The temperature was invariably found to sink in a few days so as to induce reconvalescence.

"But far more remarkable was the influence exerted by the chloroform treatment upon the sensory organs. Numbness, the specific typhoid face and expression, and hardness of hearing, disappeared under this treatment in three to four days; the patients grew lively and cheerful, and nothing short of an actual measuring of the temperature would have betrayed the presence of the insidious malady. The author ascribes this favorable influence of chloroform over the typhoid process, not to any disinfecting properties of the drug itself, but to the products of its chemical decomposition within the system."

The writer adds:

"In England chloroform is considerably used for internal purposes. The British Pharmacopœia has three preparations of it, viz.: Aqua chl. (1 to 200), spiritus chl. (1 to 20), and tinctura chl. comp. (2 to 8 spir. rect., 10 tinct. card. co.). The spiritus chl., particularly, is often used, in ten to sixteen drop doses, as a favorite adjunct to various mixtures, in view of its sedative, narcotic, and antispasmodic virtues. It is also used in England in malaria when quinine has failed."

Chloroform had been recommended long ago for fevers (*Medical Press and Circular*, 1854, vol. i., p. 114), and it has been tried without much success in cholera.

THE PATHOLOGY OF EXOPHTHALMIC GOITRE.

The pathological changes upon which this interesting disease depends are so obscure that no one has been able hitherto to determine even in what part of the body they occur.

Observation has taught us that in all probability they are not located in the organs which are most prominently affected—the heart, the eyes, and the thyroid gland—but that their seat is some part of the nervous system. For a long time the theory most favored was that in the cervical sympathetic the essential changes would be found, but this part of the nervous system has so often been found healthy in this disease, and so often found affected when the symptoms of exophthalmic goitre were absent, that this view must be abandoned. Dr. White, Senior Assistant Physician to Guy's Hospital, publishes (*British Medical Journal*, March 30, 1889) a case in which he found, at post-mortem, very suggestive changes in the floor of the fourth ventricle.

The patient, a woman, thirty-one years of age, whose mother had died at the age of twenty-one of rheumatic fever, had had two attacks of "ulceration of the bowels," the last two years before the record begins. Since this last illness she had not been strong. For nine months she had been losing flesh. For ten days she had taken little food. She had had cardiac palpitations for many years, and goitre for twelve years. Eyeballs were slightly prominent, with Graefe's sign; optic disks normal; pulse 150; bowels regular, menses irregular, urine normal. In spite of treatment diarrhœa, jaundice, and pneumonia on the right side set in, and the patient soon died.

At post-mortem, very little fat on the body, but a normal amount in the orbits. Cervical glands slightly enlarged; thymus easily recognized but not enlarged; thyroid extremely enlarged uniformly. In lungs, confluent lobular pneumonia at both bases. Heart eleven ounces; no sign of microscopic fatty change. Stomach, large and small intestines all intensely congested, with swelling of the mucous membrane; the solitary follicles more prominent than usual. Liver, kidney, and suprarenal capsules normal; mesenteric glands all swollen and injected. The capillaries of the interior of the brain were everywhere full, especially *on the floor of the fourth ventricle*.

For microscopic examination, a series of sections was made, extending from the lowest part of the medulla to the corpora quadrigemina. At the level of the lower part of the olivary nucleus there was, just under the posterior surface of the medulla, evidence of slight inflammation, shown by engorgement of the vessels, blood being present in their sheaths, and by a few wandering cells in the posterior median nucleus on each side. The next few sections were healthy, but those near the nucleus of the sixth nerve showed considerable changes. Just under the posterior surface of the medulla, from the middle line to the restiform bodies, which were slightly involved, were numerous hemorrhages. The area occupied by these did not extend deeply, so that, except for a slight implication of the sixth nucleus on one side, the nerve-cells had escaped injury. Also, the fibres of the facial nerve, which approach the surface here, were free. The hemorrhages seemed almost entirely limited to the posterior superficial part of the reticular formation, but there were two or three small deeper ones. Though most marked at this level, they existed in all sections up to the lower part of the aqueduct of Sylvius, where, however, only one or two were seen. They always occupied the posterior part of the reticular formation. The hemorrhages were not old, but had not occurred immediately before death. The cervical sympathetic cord was quite healthy. In the superior cervical ganglia the nerve-cells were healthy, the sections were full of leucocytes.

The hemorrhages were visible to the naked eye, and none of those present at the examination had ever seen them so marked in the medulla.

Dr. White supposes that these hemorrhages occurred as a result of the pneumonic fever from which the patient suffered. He infers that, since the hemorrhages would naturally take place in that part of the central nervous system which was rendered weak by local disease-changes, they indicate the seat of the pathological processes which underlie the various symptoms of exophthalmic goitre—processes so subtile that they may not be, as yet, traced by the most careful microscopic examination.

A New Bill for the Commitment of Lunatics.—A bill providing a new mode for the commitment of lunatics has passed the State Legislature and is said to be now before the Governor for his signature. It contains several provisions which are of most questionable value. It throws the chief responsibility upon the judge, and offers to the supposed lunatic opportunity for jury trial. The bill will make the process of commitment very cumbersome and expensive, and it is to be hoped that it will not become a law until it has been amended. The present law is believed to act very well.

News of the Week.

DIFFICULT QUESTIONS TO ANSWER.—The following questions were asked at the recent examination of Bishop's case: "How can anyone tell that a post-mortem examination has been made before death?" "Is *rigor mortis* a sure sign of death?"

WHAT MAY OCCASIONALLY HAPPEN TO ONE WHO READS "THE RECORD" ON THE CARS.—An esteemed correspondent writes: "Before publishing any more cuts similar to the ones on page 593 of the last number of THE RECORD, please print 'warning' or 'danger' on the preceding page. Yesterday afternoon I started for New Haven, and stuck last week's RECORD in my pocket to read. Seated comfortably upon the lounge seat in the parlor-car, facing all the rest of the passengers, I began reading the paper systematically, and turning leaves gradually without looking ahead. While reading page 592, and holding THE RECORD straight up to get a good light over my shoulder, I noticed that a young lady seated about four feet away suddenly concentrated her attention upon THE RECORD. Supposing that she was simply trying to read the title I paid no attention, but kept on reading. Looking up again, I observed that all of the passengers within twenty feet of me were spellbound. I turned to the next page to see what was the matter, and was confronted by a series of yawning chasms. I got up calmly and went into the smoking compartment, and *stayed there*."

THE MIND-READER DIED IN A NATURAL WAY.—The sensational examination by the Coroner into the cause of death of the mind-reader, Bishop, has turned out as we expected it would. It will be recollected that it was charged that the gentlemen who made the examination of the body for pathological purposes did so before life was extinct, and that the subject was in a state of catalepsy. After a very thorough examination into the matter by the Coroner, both Drs. Ferguson and Irwin were duly exonerated. This was a foregone conclusion to the medical public, and amply justified by the reputation of the gentlemen concerned.

COMMENCEMENT WEEK AT YALE.—Professor H. C. Wood, M.D., of Philadelphia, will deliver the annual Address in Medicine at Yale University on Tuesday, June 25th, at 12 M.

A HOSPITAL FOR DARTMOUTH.—Mr. Hiram Hitchcock has given to Dartmouth College a hospital, which is to be attached to the Medical School of that institution. The plans for the new building are still in the hands of the architect, but it is expected that the structure will be completed within a year. The ground has been purchased in Hanover, and everything is now in readiness to proceed with the work as soon as the plans shall have been approved. Mr. Hitchcock was led to make this gift by an appreciation of its necessity and by a desire to establish a fitting memorial to his late wife, the hospital being given and accepted as such. It will be the handsomest and best equipped institution of the kind in Northern New England.

THE NEWPORT CITY COUNCIL has appropriated $300 for the entertainment of the American Medical Association next month.

DR. HOWARD KELLY, for a year connected with the department of obstetrics at the University of Pennsylvania, has been elected to the chair of obstetrics at Johns Hopkins University.

THE PROPOSED MEMORIAL TO THE LATE PROFESSOR MOSES GUNN.—The Alumni and Faculty of Rush Medical College, Chicago, have been for some time engaged in the effort to raise by subscription a fund for the purpose of erecting in the college building a bronze to serve as a memorial of the late Professor Moses Gunn.

THE MEDICAL SOCIETY OF NEW JERSEY will hold its next annual meeting in the Coleman House, at Asbury Park, on June 18 and 19, 1889, commencing at 4 P.M. of Tuesday, June 18th. President, H. Genet Taylor, M.D., Camden; Secretary, William Pierson, M.D., Orange, N. J.

A NEW CASE OF LEPROSY is reported to be at the Harlem Hospital in this city.

THE MAINE MEDICAL ASSOCIATION.—The thirty-seventh annual meeting will be held at Portland, on Tuesday, Wednesday, and Thursday, June 11th, 12th, and 13th.

DRS. HORTON AND WILLETTS, two physicians of Huntington, L. I., were arraigned at Jericho last week, charged by Dr. Watson, health officer of that town, with failing to report some cases of scarlet fever which they had been called to attend.

SUMMER HOTELS AND CIRCULAR DISTRIBUTORS.—The profession are now in the hands of the circular distributors, who are exhausting the arts of both the wood-engraver and rhetorician. The former usually perches his sanætarium upon the top of a wooded hill, fast by which flows a pearly stream, and the latter furnishes glowing word-pictures of earthly paradises where trout abounds.

SUIT FOR DAMAGES BY A MEDICAL AUTHOR.—Dr. Herbert Tibbitts has brought a suit against Messrs. MacMillan, the publishers, on account of an unfavorable review upon a work on massage written by Dr. Tibbits, and appearing in the pages of *Nature*. The surest way to prevent similar mistakes in future is to have authors write their own reviews.

PRELIMINARY PROGRAMME OF THE ASSOCIATION OF AMERICAN PHYSICIANS, to be held at the Army Museum Building, Washington, D. C., on September 18th, 19th, and 20th: 1. The President's Inaugural Address, Francis Minot, Boston, Mass. Discussions: 2. "The Relations between Chlorosis, Simple Anæmia, and Pernicious Anæmia, including Leucocythæmia and Hodgkin's Disease," *Referee*, Frederick P. Henry, Philadelphia, Pa.; *Co-referee*, F. Forchheimer, Cincinnati, O. 3. "The Relation of Rheumatism to Rheumatoid Arthritis," *Referee*, William Osler, Baltimore, Md.; *Co-referee*, M. Longstreth, Philadelphia, Pa. Papers: 4. "Primary Cancer of the Duodenum," by E. N. Whittier, Boston, Mass. 5. "Gastric Neurasthenia," by G. M. Garland, Boston, Mass. 6. "Chylous Effusion into Serous Cavities," by S. C. Busey, Washington, D. C. 7. "Etiology of Pleurisy especially in its Relation to Tubercular Disease," by A. A. Smith, New York. 8. "Thrombosis of the Cerebral Sinuses," by A. B. Ball, New York. 9. "The Early Stages of General Paralysis," by C. F. Folsom, Boston,

Mass. 10. "Tetany," by James Stewart, Montreal, Canada. 11. "Tetany and a New Theory of its Pathology," by John T. Carpenter, Pottsville, Pa. 12. "Migraine—Its History, Nature, and Treatment," by Wharton Sinkler, Philadelphia, Pa. 13. "Diseases Characterized by Loss of Consciousness and Coma," by Israel T. Dana, Portland, Me. 14. "Substitutes for Opium in Chronic Diseases," by J. F. A. Adams, Pittsfield, Mass. 15. "The Contagion of Diphtheria," by P. Gervais Robinson, St. Louis, Mo. 16. "The Bacillus Tuberculosis," by J. T. Whittaker, Cincinnati, O. 17. "How far may a Cow be Tuberculous before the Milk becomes Dangerous as a Food Supply?" by Harold C. Ernst, Jamaica Plain, Mass. 18. "A Supplementary Inquiry into the Frequency with which Lead is found in the Urine," by James J. Putnam, Boston, Mass. 19. "The Anatomical and Physiological Relations of Lesions of the Heart and Kidney," by H. F. Formad, Philadelphia, Pa. 20. "Specimens from two Cases of Cretinism," by W. F. Whitney, Boston, Mass.

More Malpractice Suits in California.—A short time ago Dr. Joseph Kurtz, one of the editors of the *Southern California Practitioner*, was the successful defendant in a suit for $21,000 in a case of alleged malpractice. Very recently, Dr. Walter Lindley, President of the State Medical Society, was sued for $20,000 on account of alleged malpractice.

A Large Family.—An enterprising Western newspaper, the *Arkansas Gazette*, has offered a prize to the largest family in the State, with the result of finding a Pike County couple who have had twenty-three children, of whom eighteen are still living. The prize-winners are Mr. and Mrs. W. D. Green, aged respectively seventy-seven and seventy-one years. The couple have seventy-two living grandchildren and twelve living great-grandchildren. Mr. Green, when married, lacked twenty five days of being twenty-three years of age, and at the time of the birth of his last child he was sixty-seven years, seven months, and fifteen days old. Mrs. Green, at the date of the birth of her first child, was eighteen years, four months, and six days of age, and at the time of her last child's birth she lacked eleven days of being sixty-two years old. The children were all born singly. The facts are certified to by an affidavit.

It is Said that Canon Wilberforce has been cured of a dangerous ailment by prayer and the anointing with oil, and that he has practically joined the ranks of the Peculiar People, or as they are called in this country, Faith-Healers.

The American International Congress of Medical Jurisprudence held its first meeting under the auspices of the Medico-Legal Society of New York, at Steinway Hall, this city, June 4, 5, 6, and 7, 1889, Lieutenant-Governor Edward F. Jones in the Chair. Addresses of welcome were made by Clark Bell, Esq., Hon. Chauncey M. Depew, Ex-Judge John F. Dillon, Ex-Judge Noah Davis, Hon. John S. Wise, Hon. John R. Fellows, Simon Sterne, Esq., Roger Foster, Esq., Moritz Ellinger, Esq. In the afternoon session of Tuesday, the following papers were read: "History of the Marsh Test for Arsenic and Modifications of the Same," by Professor R. O. Doremus; "Nouveau Procédé pour la Recherche des Cristaux de l'émine du Sang Humain," by Dottor C. Spadaro, Puglia, Italy; "The Medico-Legal Points in Case of State of Michigan vs. Matthew Millard," by Professor V. C. Vaughan, of Ann Arbor, Mich.; "Electrical Distribution," by Harold P. Brown, Esq., of New York City; "Sources of Error in Micro-measurements in Medico-Legal Cases," by William J. Lewis, M.D., of Hartford, Conn.; "Medico-Legal History of the Deschamp Case; Was it Rape, Insanity, or Murder?" by Y. R. Le Monnier, M.D., Coroner of New Orleans, La. The following subjects were introduced on Wednesday: "Criminal Responsibility in Narcomania," by Norman Kerr, M.D., of London; "Alcoholic Trance," by T. D. Crothers, M.D., of Hartford, Conn.; "License Laws," by Carl Horsch, M.D., of Dover, N. H.; "Drunkenness, its Influence on Morals," by T. L. Wright, M.D., of Belfontaine, O.; "Suicide," by William Lane O'Neill, LL.D., of New York; "The Legal Responsibility of the Criminal Insane," by Judge H. M. Somerville, of the Supreme Court of Alabama; "The True Legal Test of Responsibility of the Insane," by Judge M. W. Montgomery, of the Supreme Court, Washington, D. C.; "Feigned Insanity," by Connolly Norman, M.D., of Ireland; "Eccentricities of Insanity," by ex-Chief Justice Noah Davis, of New York City; "Volitional Insanity," by Austin Abbott, Esq., of New York City; "The Disposition to be made of Criminal Lunatics," by W. W. Godding, M.D., of Washington, D.C.; "Change of Character a Legal Criterion in Insanity," by C. H. Hughes, M.D., of St. Louis, Mo.; "The Criminal Insane," by Samuel Wesley Smith, M.D., State Commissioner in Lunacy of New York; "Separate Hospitals for Insane Convicts," by Clark Bell, Esq., of New York. On Thursday the following papers were read: "The Legal Aspects of Hypnotism," by Benno Loewy, Esq., of the New York Bar; "A Study of the Skulls of Criminals," by Frederick Peterson, M.D., of New York City; "Mental Epidemics," by Moritz Ellinger, Esq., of New York; "Some Forensic Features of Psychology," by Edward P. Thwing, M.D., of Brooklyn; "Freedom of the Will," by C. A. F. Lindorme, M.D., of Florida; "Philosophy of Criminal Law," by Rev. William Tucker, LL.D., of Ohio; "Power to Transmit and Record Language," by R. S. Guernsey, Esq., of the New York Bar; "The Abolition of the Coroner in Massachusetts," by Theodore H. Tyndale, Esq., of the Boston Bar. In the afternoon an excursion was enjoyed to the New York City Institutions for the Insane, as guests of the Commissioners of Charities and Corrections of the City of New York. The session continued during Friday, with the following papers: "Medical Expertism in the Old World," by A. Wood Renton, Esq., of London; "Expert Testimony in Homicide Cases," by Judge William H. Francis, of Dakota; "Medical Expertism considered from its Legal and Medical Standpoint," by T. Gold Frost, Esq., of the Minnesota Bar; "An Ideal Asylum for Insane in a new State," by Stephen Smith, M.D., of New York City; "Shall we have an American Penal Colony?" by H. S. Drayton, M.D., of New York City; "Live Birth in its Medico-Legal Relations," by Professor John J. Reese, of Pennsylvania; "Life Insurance," by Hon. Daniel Jordan, of Fredericton, N. B.; "Abortion," by a member of the Medico-Legal Society.

Society Reports.

THE ILLINOIS STATE MEDICAL SOCIETY.

Thirty-ninth Annual Meeting, held in Jacksonville, May 21, 22, and 23, 1889.

FIRST DAY, TUESDAY, MAY 21ST—MORNING SESSION.

THE Society was called to order by the President, CHARLES WARRINGTON EARLE, M.D., of Chicago, Ill., at 10 A.M., in the Young Men's Christian Association Hall.

The REV. A. B. MOREY offered prayer.

The address of welcome was delivered by City Attorney RICHARD YATES, son of the old war Governor.

The response, in the absence of Dr. B. F. Griffith, of Springfield, was made by DR. N. S. DAVIS, SR., of Chicago, which was listened to with rapt attention.

DR. T. J. PITNER, Chairman of the Committee of Arrangements, made a number of announcements, after which the President called for the

REPORT OF THE COMMITTEE ON REVISION OF THE CONSTITUTION,

DR. T. M. MCILVAINE, of Peoria, Chairman.

The report was discussed by Drs. Davis, of Chicago; Powell, of Collinsville; Herriott, of Jacksonville; Ingals, Earle, and Graham, of Chicago; Darrah, of Bloomington; Leeds, of Lincoln; Ensign, of Rutland; Hunt, of Dixon; Carter, of Waukegan; Barnes, of Bloomington; and Matthews, of Collinsville. The matter, on motion of Dr. Graham, was referred back to the same committee, with Drs. Davis and A. K. Van Horn, of Jerseyville, as additional members.

On motion the Society adjourned.

AFTERNOON SESSION.

The Society was called to order by the President.

DR. F. C. ROBINSON, of Wyanet, Chairman of the Committee on the Practice of Medicine, then made his report, which was followed by a paper on

THE TREATMENT OF PNEUMONIA,

by DR. GEORGE N. KREIDER, of Springfield.

Dr. Kreider said that during the past few years much had been written about the mortality of pneumonia. Men whose experience has extended for a long period of years affirm that the death-rate is much higher under the present accepted modes of treatment than it was forty years ago, when the pathology of this disease was almost unknown. He advanced the following conclusions: 1. That baths should only be given in those cases which are not progressing favorably. 2. In severe cases nothing is calculated to give so much relief to all bad symptoms. 3. Rules for selecting cases and administering baths cannot be rigidly given. The thermometer is not always a guide for their administration. Difficulty of respiration and lack of secretion should lead to its employment regardless of the height of the mercury. 4. The bath should be given at a temperature of 100° F. or less, depending on the severity of the case and the condition of the patient. Baths of extremely low temperature I have not found necessary as yet, but I should not hesitate to employ them if occasion should require. 5. Stimulants should be given just before entering and in coming out of the bath-tub. The patient should not exert himself in the least. 6. The physician should himself superintend and aid in giving the bath. This rule can only be broken by having trained nurses who are competent to meet emergencies which might arise. 7. The bath treatment is capable of shortening the duration of the disease and convalescence, and of reducing the mortality. Lebermeister says it has been reduced in his hands from twenty-five to ten per cent. The ice-coil will be found effective in the milder cases in reducing temperature and relieving pain, if placed directly on the affected side.

DR. J. M. G. CARTER, of Waukegan, said he had listened with interest to the papers. Anything which will tend to equalize the circulation in pneumonia would be beneficial. Whenever a hot or cold bath or local application will accomplish that purpose it is a good remedy. With regard to diphtheria, he had been unable to determine its contagiousness. In the treatment he used aconite to reduce temperature; belladonna to control the condition of the throat and to act as an anodyne, because most sore throats occurred in children. He gives them chlorate of potash mixed with sugar. He does not recommend gargles, except where they can be used easily.

DR. J. S. MILLER, of Peoria, had seen but two well-defined cases of diphtheria during the last three or four years. He would refer to one as "masked" diphtheria, because he treated the case three or four days before he was able to make a diagnosis, and it was only a few hours before the death of the patient that he was able to find out the true condition. The symptoms were those of fever, difficulty in breathing; unable to detect any lung trouble. A few hours before the death of the child he discovered diphtheritic membrane clinging to the throat. A great deal of attention should be paid to diagnosis in such cases. Relative to treatment, he was of the opinion that time is one of the most important factors. If we can gain time we do more toward guiding the case to a successful issue than by medication, and in order to gain time he favors the supportive plan of treatment. He does not believe in specifics in diphtheria. Iron, quinine, and whiskey should be given to prevent the destruction of tissue. One of the valuable local applications is ice, which, by acting on the tissues, produces contraction and hastens disintegration of the membrane. He had discontinued local applications to the throat entirely.

DR. W. M. BARRITT, of Onarga, in the treatment of diphtheria impresses the system as early as possible with some antiseptic, preferably the biniodide of mercury, it being more diffusible than some other forms; and in early childhood, where it is not possible to make applications locally, we must depend mainly upon constitutional treatment. Sulphurous acid, administered internally, gives good results.

DR. E. L. HERRIOTT, of Jacksonville, is satisfied with the old style of treatment in pneumonia. He commences with quinine and general supportive treatment; then applies a genuine fly-blister, and in connection with the blister he uses either the muriate or carbonate of ammonia, whichever he deems best.

DR. J. TOWNSEND, of Springfield, said that tepid applications were very beneficial in reducing the temperature in pneumonia. He had seen numerous instances in which the use of the coil in cases of puerperal fever and typhoid fever proved very beneficial, reducing the temperature from a dangerous point to one in which the patient passes along through the disease without danger from death. He had known Dr. Kreider to use cold applications in a great many instances with beneficial results.

As regards the matter of temperature, there is much irregularity. Cases, said the speaker, are on record where the temperature has reached 125°, which, in his opinion, were due to hysteria.

THE PRESIDENT said that if the statement of the last speaker were true—viz., that a temperature had been reached of 125° in the case of some patients of the Central part of the State, it would make physicians from the North feel a little dizzy.

DR. W. T. THACKERAY, of Chicago, said there was no question but that antipyrin reduces temperature rapidly; but the ill-effects upon the stomach and the depressing influence upon the nervous system lead physicians to question its value as an antipyretic. He discarded it very early, and has not given a dose of it in three years. He had never known it to maintain an excessively low temperature, say 96° or 97°. He would look upon it as an exception if it was maintained for any length of time. He had known Dr. Byrd, of Quincy, to use the cold pack with excellent results.

He was surprised to hear Dr. Townsend speak of a temperature of 125°, and life remain afterward. He had always been taught that a temperature of 109° was fatal, and if it got a few degrees beyond that the blood itself would become coagulated in the blood-vessels, and it would not be possible for life to continue. He would like to know where Dr. Townsend got his authority.

Dr. Kreider said the statement made by Dr. Townsend was absolutely correct, and could be found in Sagand's work entitled "Thermometric Observations." It could also be found in Wagner's "Pathology," a reprint from Sagand's book.

Dr. David Prince, of Jacksonville, would like to refer to the question of temperature in a briefer way, and how heat and cold act. The cold coil is applied to a patient with inflammation of the brain, and relief is afforded; a hot coil is applied, and there is relief, and afterward the patient is asked, "Which will you have?" And he says, "I will have the hot." The same application to the eye or ear affords relief. It is evidently not the amount of caloric heat abstracted from the body, but some local influence which is transmitted to some other centre which results in the contraction of the vessels in both instances.

With reference to the treatment of diphtheria, the best success he had ever seen was by the use of a spray of Lugol's solution. He had seen some remarkable recoveries from this spray. In an epidemic he had once used bromine in the same way, supposing it was a better antiseptic than iodine, but his practice did not bear out the anticipation.

Dr. A. J. Baxter, of Astoria, is in the habit of giving warm baths in pneumonia, also in cases of typhoid fever, alternated with cold, and he finds almost as much benefit from one as the other.

In regard to antifebrin and antipyrin, much depends upon the system as to the manner in which they should be used. In very nervous patients he is more cautious in administering them than in those of a robust constitution.

Dr. L. L. McArthur, of Chicago, said that the variety of abscess of the lungs which results from pneumonia is simply of a suppurative character, non-tubercular, and too frequently a diagnosis is not made. In addition to the treatment recommended by Dr. Robinson, it is now considered good practice to open such abscesses of the lungs and drain them, as in any other portion of the body.

The papers were further discussed by Drs. E. P. Cook, of Mendota, A. F. Lee, of Quincy, S. T. Hurst, of Greenview, and discussion closed by the essayists.

Dr. A. J. Baxter, of Astoria, read a paper on

DYSPEPSIA.

Dr. N. S. Davis, of Chicago, said he knew of a great many conditions of the digestive organs that go under the general designation of dyspepsia, but they were as diverse from one another as hot water is from an ice-pack. The only success he has in treating such cases is to analyze each case on its merits, and if he finds out the habits and pathological condition of the digestive organs and rationally adjusts his treatment accordingly, he finds generally but little difficulty in curing them.

The paper was further discussed by Dr. A. Wetmore, of Waterloo.

Dr. J. L. White, of Bloomington, read a paper entitled

HYGIENE AND DOCTORS' FEES,

which was discussed by Drs. Kreider, Davis, G. L. Eyster, of Rock Island, and closed by Dr. White.

Second Day, Wednesday, May 22d—Morning Session.

The report of the Committee on Diseases of Children was made by Dr. A. T. Darrah, of Bloomington.

Under the general term of

SUMMER COMPLAINT,

a very unscientific but common term, are grouped such diseases as diarrhœa, dysentery, cholera infantum, enterocolitis. Of the great mortality of children under the age of five years, vital statistics show that a large per cent. is caused by bowel diseases during the hot weather. This is especially marked in the larger cities of the Central and Southern parts of the United States. Philadelphia may be taken as an example. Here the mortuary records show that deaths from these causes are at a minimum during the months of December and January, and that during the months of July and August the maximum death-rate is reached.

Heat weakens by destroying the cohesive force between atoms. The result is a relaxed and flabby condition of the tissues. Continuous high temperature, acting upon the very delicate nervous organization of children, has the effect of either destroying the digestive ferment of the stomach, otherwise its natural secretion is arrested, normal digestion ceases, and the abnormal condition of fermentation may take its place. Heat being the prime factor in the causation, and acting through the sympathetic nervous system, we should counteract its effects, hence *cold* is the remedy. By reducing the temperature, the cause of the disease is removed. We should not wait for the little ones during warm weather to become sick, but begin the use of tepid bathing, cool or cold water. Use it freely, and let it be of a temperature suited to each individual case. If these suggestions were acted upon, and a more liberal use of the remedies at hand employed, the lives of many children would be saved.

Dr. A. E. Hoadley, of Chicago, said after an experience of twelve years in treating diarrhœa in infants he could speak of the utility of the treatment advocated by Dr. Darrah. In his practice he teaches families to keep the babies cool, and they do it in this way: Just as soon as they begin to feel the effects of heat, faces red, and heads tossing about, crying, etc., instead of giving them extra food of some kind, part of their clothing is removed; if it is excessively hot, they take off more. The children are then wiped down with tepid water, and allowed to lie on the floor naked, if sufficiently hot, and there they may remain all day. Toward evening, when the weather becomes cool, their clothing is put on. With this line of treatment the children had no diarrhœa, indigestion, or any trouble during the summer. He is rarely called to see a case of acute diarrhœa in infants during the summer.

Dr. Robinson, of Wyanet, called attention to the fact that many parents refused children water to drink when they have diarrhœa. He advocates giving them all the water they can possibly drink.

Dr. Baxter said that the diet was of as much importance as medicine in the treatment.

The treatment was further discussed by Dr. Davis, at great length.

Dr. W. T. Thackeray, of Chicago, presented his report as chairman of the Committee on Drugs and Medicines.

He said that among the most important introductions during the year is that of Professor Pribram, of Berlin—viz., *agaricine*, an alkaloid from the polypory officinals, white agaric, touch-wood, tinder from the torch-tree. This fungus was originally employed by Andral as a remedy against night-sweats, and has obtained some reputation in this direction in Europe. In America, however, the agaric was only used to a limited extent as a purge. It was early discovered that two distinct resins were contained in the fungus, one practically insoluble, and the other soluble in alcohol and chloroform, the product being a yellow crystalline powder and containing what medicinal virtue was possessed by the drug. From this principle Pribram isolated the alkaloid agaricine, and he epitomized his experience with it as follows: It always decreases the sweat; thirst and the excretion of urine are diminished under its use; the functions of the lungs and skin are not interfered with; it gives no after ill-effects.

Dr. Thackeray finds in his practice that it acts just as perfectly as stated by Pribram, in the dose of two milli-

grammes, not once only, but in several cases. He had other reports, however, where it was necessary to use as much as eight milligrammes before the effects were produced, but in all such cases success attended the administration.

A paper entitled "Notes on the Causes and Management of Hernia in Infants and Young Children," by DR. K. MILLER, of Lincoln, was read by DR. LEEDS, in the absence of the author.

The next thing in order was a paper on

VAGINAL HYSTERECTOMY,

by DR. H. T. BYFORD, of Chicago, which was read by DR. F. H. MARTIN, in the absence of the former.

Dr. Byford commences by saying that one of the greatest and most astonishing of the many triumphs of modern gynecological surgery is the development of vaginal hysterectomy. The death-rate of recent vaginal hysterectomies is about ten per cent., while that of some operators is even lower and steadily decreasing. The steps of the operation are as follows: 1. An incision is made through the vaginal wall extending in a circular direction two-thirds the distance around the cervix in front and at the sides; 2, separation of the parametric tissue from the uterus up to the uterine arteries at the side, and the bladder from the uterus in front until the peritoneum is reached; 3, completion of the circular incision behind the cervix; 4, opening the peritoneal cavity posteriorly and anteriorly; 5, ligation or clamping of broad ligaments, and severing them from the uterus; 6, tamponment of the vagina with iodoform gauze.

The speaker would favor giving vaginal hysterectomy a trial for all cases of uterine cancer, and particularly in cases discovered early, because it is chiefly in early cases we can expect to get beyond the disease and must make our best endeavor. In view of the diminishing death-rate he would perform the same operation for small fibroids which resist treatment and show a tendency to rapid growth, or produce incurable distressing symptoms. Occasionally cases of adenoma uteri, metrorrhagia, displacements, etc., may require the operation, not to cure a fatal disease but to relieve from a life of suffering and invalidism otherwise unavoidable.

DR. C. TRUESDALE, of Rock Island, read a paper on the

ETIOLOGY AND PATHOLOGY OF UTERINE DISPLACEMENTS.

He summarized his remarks as follows: 1. The normal typical position of the uterus in the pelvis, in an erect position of the body, instead of being upright is nearly horizontal. 2. Anteversions of the uterus, so-called, pathologically have no existence. 3. The body of the uterus is supported by the bladder, the bladder upon the vagina, the vagina upon the perineal septum as far back as the rectum, the neck suspended by the utero-sacral ligaments on a plane as high as the body with the empty bladder. 4. All ordinary displacements, such as prolapsus, anteflexion, retroversion, and retroflexion, are produced by contracture of the muscular walls of the vagina.

DR. FRANKLIN H. MARTIN, of Chicago, read a paper in which he reported

THREE CASES OF FIBROID TUMORS OF THE UTERUS OPERATED UPON BY APOSTOLI'S METHOD,

which illustrated the three different procedures of the method, viz.: 1. Intra-uterine galvano caustic—positive operation. 2. Intra-uterine galvano-caustic—negative operation. 3. The intra-vaginal galvano-puncture operation.

He also gave a short summary of results obtained by himself in a series of one hundred consecutive cases treated by Apostoli's method, which were as follows: 1. Of the hemorrhagic cases, ninety-five per cent. were cured of hemorrhage. 2. Tumors entirely disappeared in eighty per cent. 3. Tumors were reduced in size in seventy-eight per cent. 4. Tumors not affected in size, either from failure of treatment or from patients discontinuing treatment or for other reasons, fourteen per cent. 5. Neuralgic and other pains relieved in ninety per cent. 6. No deaths. 7. Symptomatic cures, sixty-eight per cent. (these sixty-eight not including the eight actual cures).

DR. L. L. MCARTHUR, of Chicago, read a paper on

UTERO-VAGINAL FISTULA, AND TREATMENT,

with report of a case. He emphasized some points in the technique of the operation, as follows: 1. Suturing in the longitudinal rather than in the transverse diameter of the vagina, because there is less contraction on the stitches and greater facility in introducing them. 2. Choice of sutures varies with many, though silk-worm gut has perhaps the preference—Sims, Bozeman, and Haegar preferring silver wire. Pippingsjeld claims excellent results from the use of alternate silver and iron wire, believing that the galvanic current thus induced plays an important part in the union. Excellent results are on record with silk as the suture. 3. Until Simon, who, perhaps, did more than any other operator to simplify the treatment, demonstrated that it was neither necessary to retain a catheter in the bladder after operation nor to maintain the reclining posture. He permits his patients to rise as soon as they feel disposed, simply requiring them to empty the bladder at least every two hours. 4. Render the urine aseptic by some such agent as saccharine benzoic acid, or boracic acid internally. 5. That if the first operation succeeds in locating the orifice of the fistula on the mucous surface of the bladder, that constitutes one step of some operators' methods, who then at a later sitting close the bladder opening. 6. That any colored liquid may be used to differentiate the fistula, as those above mentioned. 7. It is not necessary to put off the cure until the age of puberty is reached. 8. Encircle the orifice of the fistula with about one-quarter inch of mucous membrane. This serves to retain the ureter in the bladder and prevents by a valve-like action the escape of urine through the wound. 9. That the sphincter vesicæ in a congenital case has never been trained to its proper function and may need attention in the line of internal medication.

DR. ABBEY F. ROONEY, of Quincy, contributed a paper entitled

THE USE OF THE CURETTE IN PUERPERAL ENDOMETRITIS.

Whenever there is fever or pain, or fetor which points to this cause, the quickest and the surest way to abort the trouble is to carefully remove with a dull curette every easily detachable fragment. There need be no violence, and there should be no fear of consequences.

Dr. Rooney finds it more convenient to take advantage of Sims' position, steady the cervix with a tenaculum, bend the curette to that curve which allows it to pass the os internum most readily and find the irregular surfaces, and by this means roll out any tissue-fragments or dark clots that may be enclosed, for sometimes the cervix contracts down quite firmly, and the uterus, especially in miscarriages, appears flexed either forward or backward. After curetting she applies iodized phenol upon a cotton-wrapped applicator, which she regards as a valuable antiseptic and styptic. A Vienna physician had reported two hundred cases in which he had curetted for puerperal endometritis, with no deaths. She had never heard of such a record following the use of the uterine douche.

DR. CHARLES C. HUNT, of Dixon, read a paper entitled

CARBOLIC ACID, PURE OR IN CONCENTRATED SOLUTION, AS A DISINFECTANT IN THE TREATMENT OF PUERPERAL SEPTICÆMIA,

in which he said the following cardinal points are now generally admitted: 1. Puerperal septicæmia is of bacterial origin. 2. It is identical with surgical fever, but under exaggerated conditions. 3. It is pre-eminently infectious. 4. It is preventable.

During the spring of 1888 he had seen a great many interesting cases. He would limit what he had to say exclusively to the claims of carbolic acid, either undiluted

or in very strong solution, as a local application to the points through which diseased germs find their way into the system—namely, the lesions in the genital tract, and the interior of the uterus.

His clinical experience with undiluted or very strong solutions of carbolic acid tends to establish: 1. That it is not attended with danger. 2. That if applied early the temperature is immediately reduced. 3. That it is efficient as a disinfectant; no micro-organisms or spores can exist or develop where it touches. 4. That to apply it effectually and safely we must be guided by the sense of sight as well as that of touch.

EVENING SESSION.

DR. ROSA H. ENGERT, of Chicago, read a paper on the

RELATION OF UTERINE FIBRO-MYOMATA TO THE ORGANIZATION OF THROMBI.

In her opinion a fibroid is nothing more nor less than an organized giant thrombus. Wherever a hæmatoma happens to form, nature will try to bring life into the extravasated blood-coagula by organization. This may take place anywhere where there is sufficient vitality in the surrounding parts. The organs of generation in women, endowed by nature with extra-energetic vitality, are a fertile soil for the organization of these new formations.

To substantiate this hypothesis she then quoted from some of the latest researches in regard to the organization of thrombi. Welch, of Baltimore, writes: "In a thrombus of five minutes' existence blood-corpuscles were found, but in a state of degeneration. Leucocytes were already visible, although sparingly. Half an hour later they increased considerably in number. Fibrin appeared in from five to thirty minutes in the form of strips and islets between the blood-corpuscles and on the surface of the blood-coagula. Gradually it formed a net-work, and twenty-four hours from the beginning of the process a great part of the thrombus consisted of fibrin. Leucocytes seemed to wander about in the coagula, and the fibrin seemed to increase in proportion to the increase of these" (the leucocytes).

Heuknig holds that the "first process in the organization of a thrombus is the conversion of the blood into a fine granular mass, this being hyaline and striated. Canalization takes place from the line of demarcation on the border of the vessel-wall, proliferation of the endothelium begins, and gradually covers that part of the thrombus which does not adhere to the surrounding wall. Underneath this cover a layer of connective tissue develops. The endothelium begins to grow into the thrombus and capillaries are formed. Another set of capillaries develops from the vasa vasorum of the vessel in that particular thrombus which adheres to the vessel-wall. Gradually the connective tissue increases while the thrombus decreases."

Dr. Engert then reported some cases tending to substantiate the previously advanced statements.

DR. N. S. DAVIS presented a report on "Meteorological Conditions and their Relation to the Prevalence of Acute Diseases," which was followed by impromptu remarks on the subject of "writer's cramp" by Dr. D. R. Brower, of Chicago, during which he exhibited an appliance devised by Nussbaum.

THIRD DAY, THURSDAY, MAY 23D—MORNING SESSION.

DR. EDMUND ANDREWS, of Chicago, read a paper entitled

ONE HUNDRED OPERATIONS FOR STONE IN THE BLADDER.

He said the object of the paper is to compare the safety of litholapaxy with that of lithotrity and of lithotomy so far as his own practice is concerned. He had operated for stone over one hundred times, employing all the different methods in vogue.

The following is a summary of results: Litholapaxy (Bigelow's operation)—cases, 40; death, 1; mortality, two and a half per cent. Lithotrity (after Sir Henry Thompson's method)—cases, 6; death, 1; mortality, seventeen per cent. Lithotomy below age of puberty—cases, 55; deaths, 7; mortality, thirteen per cent. Lithotomy above age of puberty—cases, 29; deaths, 5; mortality, seventeen per cent.

In respect to the old form of lithotrity, his experience of one death in six operations is substantially like that of other surgeons. Litholapaxy can generally be performed only in adults. If we take the published statistics of adult lithotomy over the whole globe, amounting to some four thousand cases, the average mortality varies from twelve to eighteen per cent., while litholapaxy in Chicago—at least in his practice, forty cases—had a death-rate of only two and one-half per cent. The most remarkable success claimed for lithotomy comes from the warmer regions of Asia, where calculi seem to be very abundant.

The following are gathered from authentic sources: Baboo Ram Norain Das Bahadore, of India—cases, 248; deaths, 17; mortality, seven per cent. Dr. Kerr, American Hospital, China—cases, 187; deaths, 19; mortality, ten per cent. Dr. Nishnan Altoungan, Amasia, Asia Minor (educated at the American Mission)—cases, 265; deaths, 5; mortality, two per cent. Dr. Sewny, of Livas, Asia Minor—cases, 40; death, 1; mortality, two and one-half per cent. Total number of cases, 740; deaths, 42; mortality, six per cent.

DR. A. E. HOADLEY, of Chicago, read a paper on

TUBERCULAR JOINT DISEASE.

He said this is by far the most common joint affection in early life, as well as the most disastrous, which claims our attention. Tuberculous inflammations of joints are also characterized by the rapidity with which they run their destructive course. Three or four weeks is sufficient time for tubercular inflammation, if complicated with staphylococcus, to completely destroy all the elements of a joint—synovial membrane, ligaments, cartilages, bones—rendering the entire joint a chaotic mass which communicates with the outside by several openings. The disease may have its starting-point in the epiphyseal cartilage or in the synovial membrane, and in the bones themselves, but never in the articular cartilage or the articular ligaments. Both the latter are readily destroyed by infection. In seventy-seven per cent. of all cases, whether rapid or slow, the affection remains local; in the remainder the tuberculosis becomes general.

Dr. Hoadley emphasized the fact that early, thorough, and repeated aseptic operations is the treatment for this class of cases. There is at the present time but one fixed rule in regard to the kind of operation to be performed, and that is to remove all the diseased tissue, in whatever structure it may exist, and sacrifice nothing; that is, remove any healthy tissue, bone especially, that is unquestionably in the way and liable by its presence to interfere with obtaining the best results. Excision of joints in these cases, as a rule, is objectionable, because of the unnecessary amount of healthy bone removed; complete enucleation of the synovial membrane, together with such diseased portions of bone as may exist, gives the best results. The operation should be repeated as often as it becomes evident that the disease is still in progress.

DR. H. M. STARKEY, of Chicago, made the

REPORT OF THE COMMITTEE ON OPHTHALMOLOGY AND OTOLOGY.

He directed attention to the advisability of having the eyes examined in every case of persistent headache not relieved by the ordinary medical means, even when the eyes are not obviously at fault.

DR. GALEZOWSKY called attention to the close relation between some eye troubles and irritation of the upper teeth. The only new drug that seems to have met with any special favor is the antiseptic creolin.

Dr. Isadore Berrman recommends the use of lactic acid in from ten to thirty per cent. solution, for cases of chronic suppurative otitis that have resisted all other treatment.

Dr. Lyman Ware, of Chicago, read a paper on

SYPHILITIC CYCLITIS,

and reported several cases. He offered the following suggestions: 1. Greater care in the diagnosis of primary symptoms. However difficult it may be to diagnosticate primary or secondary syphilis, it is generally far more difficult to diagnosticate tertiary. It is much too common for a physician to say to his patient: "I do not think you have syphilis, but yet a little constitutional treatment will do no harm." 2. Mercury is unquestionably indicated in the primary and secondary stages, while potash in large doses is the remedy in the tertiary stage—and gummata certainly belong to the last. 3. Large doses of potash can only be tolerated when given in gradually increasing doses, preferably half an hour to an hour after meals, in much water; the freer the perspiration the larger the doses of potash.

OFFICERS FOR 1890.

President—Dr. John Wright, of Clinton; *First Vice-President*—Dr. J. P. Matthews, of Collinsville; *Second Vice-President*—Dr. T. M. Cullimore, of Jacksonville; *Permanent Secretary*—Dr. David W. Graham, of Chicago; *Assistant Secretary*—Dr. Lyman Ware, of Chicago; *Treasurer*—Dr. Thomas M. McIlvaine, of Peoria.

On motion the Society adjourned to meet in Chicago in May, 1890.

CONNECTICUT STATE MEDICAL SOCIETY.

Ninety-eighth Annual Meeting, held at Hartford, Conn., May 22 and 23, 1889.

FIRST DAY, WEDNESDAY, MAY 22D.

The meeting was called to order at 1 P.M. by the President, Dr. George L. Porter, of Bridgeport.

The Treasurer, Dr. W. W. Knight, reported a balance of $277.24 on hand.

ELECTION OF OFFICERS

resulted as follows: *President*, Dr. O. Brown, of Washington; *Vice-President*, Dr. Melancthon Storrs, of Hartford; *Treasurer*, Dr. W. W. Knight, of Hartford; *Secretary*, Dr. N. E. Wordin, of Bridgeport; *Delegates to the Meeting of the Pharmaceutical Association in* 1890, Drs. C. A. Lindsley, F. J. Young, and O. J. D. Hughes; *Delegates to American Medical Association*, Drs. F. H. Wiggins, M. Storrs, M. A. Cremin, R. S. Goodwin, W. Cummings, J. Olmstead, C. N. Allen, E. T. Bradstreet, F. L. Smith, and William Winter. Delegates were also appointed to attend the meetings of the State Societies of Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, New York, and New Jersey.

The Committee on Matters of Professional Interest for 1890 are Drs. Henry Fleischner, C. H. Beach, and F. D. Edgerton. Dissertator, Dr. W. G. Bronson.

Dr. E. M. Moore, of Rochester, was elected an honorary member. The name of Professor William H. Welch, of Baltimore, was proposed, and according to custom was laid over for one year.

At 3.30 P.M. the Society adjourned to hold its annual banquet.

In the evening a reception was tendered to the members at the residence of Dr. W. A. M. Wainwright.

SECOND DAY, THURSDAY, MAY 23D.

The Secretary, in his report, showed the present membership to be five hundred and eight; there had been thirty-two new members admitted during the year.

Dr. L. B. Almy, Chairman of the Committee on Matters of Professional Interest, read the

REPORTS OF PHYSICIANS FROM VARIOUS PARTS OF THE STATE,

giving their experiences with antipyrine, antifebrine, phenacetine, sulfonal, and saccharine. The results with the above drugs were very similar to those which have been published in The Medical Record for the past two years.

Dr. P. H. Ingalls, of Hartford, read a paper on

UTERINE CANCER.

He placed no faith in the hereditary theory. The importance of early diagnosis was urged and the unsparing use of the knife was advised. He said the theory of local origin was becoming more prominent, but the pathology is very uncertain. He thought that possibly some time a germ might be isolated as the cause of cancer. The generally accepted causes are age, childbirth, and injuries. He quoted Thomas as saying that he never knew a case in a woman who had never been pregnant. He described the symptoms, and thought where there was the least doubt that the microscope should be called to aid. The treatment was purely surgical, but there was no hope if the disease had extended beyond the uterine tissue, and operation only increased the inflammation. He recommended good hygienic surroundings and good living, opium for pain, and a solution of permanganate of potassium for stinking discharges. He explained, and gave a history of, the different operations. Vaginal hysterectomy was, in his opinion, the proper operation.

Dr. F. E. Beckwith, in the discussion that followed, thought that either with the ligature or clamp there might be injury to the tissues that would cause sloughing, and thus expose the patient to dangers of septic complications.

Dr. J. G. Holmes read a paper on

SCARLET FEVER,

in which he showed himself to be thoroughly conversant with the disease, but offered nothing new.

Dr. Seth Hills read a paper entitled

PHTHISIS PULMONALIS.

He spoke of the contagious character of phthisis, and claimed that no one had the disease without taking it from some outside source. It was time, he said, for the medical profession to take some decisive action in regard to tuberculosis. Why was the typhoid-fever germ hunted to its death and the germ of consumption, that most widespread of germ diseases, allowed to go scot-free? The time will soon come, he predicted, when the consumptive patient will be isolated from healthy subjects.

PRESIDENT'S ADDRESS.

The President then delivered his address, in which he gave greeting to the members present and reminded them that to the present membership is transmitted the responsibility of perpetuating the prosperity of the Society. He said the most important medical event of the year had been the Congress in Paris for the study of tuberculosis, at which, after papers had been read and discussions engaged in, it was concluded that consumption was possibly, and even probably, contagious. He spoke of the opposition of ignorant people to medical interference against the spread of contagious diseases. He thought that to explain this opposition opened a wide field to the faithful student of psychology. Sickness is a factor of political economy. To decrease or alleviate sickness is an act of statesmanship. The State ought to enact laws in regard to health and sickness. Considering that our prosperity is dependent upon the common people, the conclusion is logical that no other nation is so dependent upon the health and character of its people. To how great an extent does health contribute to the success of a nation? A nation rises in greatness only as long as the people are healthy. Public health is public wealth. Sickness comes,

and the laborer becomes a burden. The approximate amount of wages for a laborer is $1.50 per day, and cost of sickness is at least $1 a day. On June 1, 1880, by statistics and computation, there were about one hundred and fifty-nine thousand people over fifteen years of age sick, and about one-quarter of that number of children. This would be a loss of about three hundred and ninety-two million dollars per year, and if a pestilence swept the land it would be vastly greater. It is now recognized that small-pox is preventable, and Boards of Health are organized for public good; yet the public ask, Does it pay? They are obliged to accept the balance-sheet of facts. The question of the future is how to prevent disease. The key to the situation is to be found in the laboratory, not in the sick-room.

Essays were read by Dr. G. H. Jenkins on "Pollution of Sources from which Water and Ice Supplies are Taken;" by Dr. C. B. Newton on "Fractures, with Suggestions as to Counter-extension and the Adapting of Splints;" and by Dr. J. F. Calef on "Chronic Pachymeningitis Interna."

The meeting adjourned at 5.15 P.M., to meet in New Haven, May 28, 1890.

New Instruments.

A NEW ANÆSTHETIC INHALER.

By HENRY FLOOD, M.D.,

ELMIRA, N. Y.

THE inhaler consists of two principal parts, a cone and a bottle to hold the anæsthetic.

The cone is made of a soft rubber ring, five inches in diameter. The rubber ring is soft, and will not injure or be uncomfortable for the patient. It is pliable enough, when slight pressure is used, to adapt itself to the contour of the face.

To the rubber ring four steel wires are fastened, equal distances apart. The wires are five and a half inches long. The other ends of these are soldered in a metal ring which is three-quarters of an inch in diameter. The metal ring makes the apex of the cone. This forms a spring frame that always takes the form of a cone. If the cone is pressed together, as when caught by a patient, as soon as the pressure is removed the frame will spring back into its original shape.

It requires only a minute or two to pin a towel around the frame, which should be done with safety-pins, or, what is more convenient, I have made a hood of towelling which fits the cone. The hood is easily pulled over the frame and pinned at the base of the cone.

To prevent air passing through the meshes of the towelling there is a second hood, made of soft rubber cloth. The rubber hood is pulled over the towelling. The rubber hood is longer than the cone, leaving a free border of an inch or more which lies on the face. During inspiration the rubber cloth acts as a valve and prevents air from rushing under the cone. When the cone and rubber hood are pressed tightly to the face air can be entirely excluded from the cone. When it is desired that air should enter the cone, it is only necessary to pull up the rubber hood, and air will pass through the meshes of the towelling.

The ring at the apex of the cone has threads cut into it to screw the cork of the anæsthetic bottle into the cone. The metal cork also screws into the anæsthetic bottle. The metal cork has a stopcock to turn off or on the anæsthetic. Through the cork are two holes which pass through the bottle-end and through the stopcock, where each of the two holes divides and turns so as to open at the lower edge of the cork, thus distributing the anæsthetic, which passes through the cork in four directions, and throws it inside of the cone against the towelling.

A small piece of absorbent cotton, pushed into the apex of the cone, will prevent the anæsthetic from dripping into the patient's face.

The anæsthetic bottle holds four fluid ounces and is graduated so that at any time the amount of anæsthetic that has been used in the cone may be known. When the bottle becomes empty it is easily unscrewed, refilled, and replaced without removing the cone from the face.

The inhaler is easily taken apart and cleaned, the soiled towel or hood is to be thrown aside to be washed, and a clean one is to take its place; the frame and bottle should be washed, and each part of the inhaler can be treated with an antiseptic fluid. This is a very important feature when practising antiseptic surgery, especially in operations about the face and neck.

I have used some inhalers made for me by George Tiemann & Co., and my experience with them has proved very satisfactory.

The anæsthetic can be given as rapidly or as slowly as desired. The stopcock gives absolute control over the quantity put into the cone, and prevents a large amount of waste, requiring one-fourth to one half as much as is generally used. I have produced complete anæsthesia with chloroform in less than three minutes, and with ether in from four to seven minutes. I have kept patients anæsthetized undergoing capital operations, for nearly an hour, using less than a fluid ounce of chloroform; and in severe and painful operations for forty-five minutes, with less than four fluid ounces of ether.

Army News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 26 to June 1, 1889.

BILLINGS, JOHN S., Major and Surgeon. By direction of the Secretary of War is authorized to make, in connection with his duties as Supervisor of Mortality and Vital Statistics of the Eleventh Census, such journeys as may be ordered by the Superintendent of the Census, provided that, in each case, the approval of the Surgeon-General shall be obtained; and provided further, that the journeys shall involve no charge against the Fund for Transportation of the Army. Par. 12, S. O. 122, A. G. O., May 27, 1889.

BROWN, PAUL R., Captain and Assistant Surgeon. By direction of the Secretary of War, leave of absence for six months on account of sickness is granted. Par. 13, S. O. 122, A. G. O., May 27, 1889.

WILSON, GEORGE F., Captain and Assistant Surgeon. His resignation was accepted by the President, and took effect May 31, 1889.

FISHER, WALTER W. R., Captain and Assistant Surgeon. The leave of absence for one month granted by S. O. No. 30, C. S., Department of California, is extended fifteen days. Par. 3, S. O. 37, Headquarters Division of the Pacific, San Francisco, Cal., May 22, 1889.

RAFFERTY, OGDEN, First Lieutenant and Assistant Surgeon. Ordered with troops for field practice to Galveston, Tex., where troops will camp for such time as may be hereafter directed. Par. 1, S. O. 29, Headquarters Department of Texas, San Antonio, Tex., May 13, 1889.

GLENNAN, JAMES D., First Lieutenant and Assistant Surgeon. By direction of the Acting Secretary of War, is relieved from duty at Willet's Point, N. Y., to take effect June 1, 1889, and will proceed to Fort Riley, Kan. Par. 5, S. O. 121, A. G. O., May 5, 1889.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending June 1, 1889:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	10	2
Scarlet fever	162	28
Cerebro-spinal meningitis	2	2
Measles	96	5
Diphtheria	131	30
Small-pox	0	0
Yellow fever	0	0
Cholera	0	0

REPORT ON THE PREVENTION OF TUBERCULOSIS TO THE BOARD OF HEALTH OF NEW YORK CITY.—The disease known as tuberculosis, and when affecting the lungs, as pulmonary tuberculosis (consumption) is very common in the human being and in certain of the domestic animals, especially cattle. About one-fourth of all deaths occurring in the human being during adult life is caused by it, and nearly one-half of the entire population at some time in life acquires it. The disease is the same, in nature, in animals and in man, and has the same cause. It has been proven beyond a doubt that a living germ, called the tubercle bacillus, is the cause and the only cause of tuberculosis. It does not seem necessary to state the facts upon which this assertion is based, for the observation first made by Robert Koch, in 1882, has been confirmed so often and so completely, that it now constitutes one of the most absolutely demonstrated facts in medicine. Tuberculosis may affect any organ of the body, but most frequently first involves the lungs. When the living germs find their way into the body they multiply there, if favorable conditions for their growth exist, and produce small new-growths or nodules (tubercles) which tend to soften. The discharges from these softened tubercles, containing the living germs, are thrown off from the body. In pulmonary tuberculosis these discharges constitute, in part, the expectoration. The germs thus thrown off do not grow outside the living human or animal body, except under artificial conditions, although they may retain their vitality and virulence for long periods of time, even when thoroughly dried. As tuberculosis can only result from the action of these germs, it follows, from what has just been said, that when the disease is acquired, it must result from receiving into the body the living germs that have come from some other human being or animal affected with the disease. It has been abundantly established that the disease may be transmitted by meat or milk from tubercular animals. The milk glands in milch-cows often become affected with the disease when their lungs are involved, and the milk from such animals may contain the living germs and is capable of producing the disease. Among stall-fed dairy cows twenty or thirty per cent. are sometimes found to be affected with the disease. Tubercular animals are also frequently killed for food; their flesh sometimes contains the germs, and, if not thoroughly cooked, is capable of transmitting the disease. Boiling the milk or thoroughly cooking the meat, destroys the germs. Although the meat and milk from tubercular animals constitute actual and important sources of danger, the disease is acquired, as a rule, through its communication from man to man. Tuberculosis is commonly produced in the lungs (which are the organs most frequently affected) by breathing air in which the living germs are suspended as dust. The material which is coughed up, sometimes in large quantities, by persons suffering from consumption contains these germs, often in enormous numbers. This material when expectorated frequently lodges in places where it afterward dries, as on the streets, floors, carpets, clothing, handkerchiefs, etc. After drying, in one way or another, it is very apt to become pulverized and float in the air as dust. It has been shown experimentally, that dust collected from the most varied points, in hospital wards, asylums, prisons, private houses, etc., where consumptive patients are present, or have been present, is capable of producing tuberculosis in animals when used for their inoculation. Such dust may retain for weeks its power of producing the disease. On the other hand, dust collected from rooms in institutions or houses that have not been occupied by tubercular patients, does not produce the disease when used for the inoculation of animals.

These observations show that where there are cases of pulmonary tuberculosis, under ordinary conditions, the dust surrounding them often contains the tubercle bacilli; and persons inhaling the air in which this dust is suspended may be taking in the living germs. It should, however, be distinctly understood that the breath of tubercular patients, and the moist sputum received in proper cups, are not elements of danger, but only the dried and pulverized sputum. The breath and moist sputum are free from danger, because the germs are not dislodged from moist surfaces by currents of air. If all discharges were destroyed at the time of exit from the body, the greatest danger of communication from man to man would be removed.

It then follows, from what has been said, that tuberculosis is a distinctly preventable disease. It is a well-known fact that some persons, and especially the members of certain families, are particularly liable to tuberculosis, and this liability can be transmitted from parents to children. So marked and so frequent is this liability, and so frequent is the development of the disease in particular families, that the affection has long been considered hereditary. We now know that tuberculosis can only be caused by the entrance of the germ into the body; and that this transmitted liability simply renders the individual a more easy prey to the living germs, when once they have gained entrance. The frequent occurrence of several cases of pulmonary tuberculosis in a family is, then, to be explained, not on the supposition that the disease itself has been inherited, but that it has been produced after birth by transmission directly from some affected individual. Where the parents are affected with tuberculosis the children, from the earliest moments of life, are exposed to the disease under the most favorable conditions for its transmission, for not only is the dust of the house likely to contain the bacilli, but the relationship also between the parents and children, especially between the mother and the child, are of that close and intimate nature especially favorable for the transmission by direct contact. If, then, tuberculosis is not inherited, the question of prevention resolves itself principally into the avoidance of tubercular meat and milk, and the destruction of the discharges, especially the sputum, of tubercular individuals. As to the first means of communication, those measures of prevention alone answer the requirements which embrace the governmental inspection of dairy cows and of animals slaughtered for food, and the rigid exclusion and the destruction of all those found to be tubercular.

For the removal of the second means of communication, *i.e.*, the sputum of tubercular individuals, the problem is simple when the patients are confined to their rooms or houses; then wooden or pasteboard cups with covers should always be at hand for the reception of the sputum. These cups are supported in simple racks, and at least once daily, or more frequently if necessary, should

be removed from the racks and thrown with their contents into the fire.[1]

The disposition of the expectoration of persons who are not confined to their rooms or homes is a far more difficult problem. The expectoration certainly should not be discharged on the street, and the only practicable means for its collection seems to be in handkerchiefs, which, when soiled should at the earliest possible moment be soaked in a solution of five per cent. of carbolic acid, and then boiled and washed. Handkerchiefs thus soiled are exceedingly dangerous factors in distributing tubercle baciili, for when the sputum becomes dry it is easily separated in flakes from the cloth, and then soon becomes pulverized and suspended as dust.

It becomes evident, from what has been said, that the means which will most certainly prevent the spread of this disease from one individual to another are those of scrupulous cleanliness regarding the sputum. These means lie largely within the power of the affected individual. It is, furthermore, to be remembered that consumption is not always, as was formerly supposed, a fatal disease, but that it is in very many cases a distinctly curable affection. An individual who is well on the road to recovery may, if he does not with the greatest care destroy his sputum, diminish greatly his chances of recovery by self-inoculation. While the greatest danger of the spread of the disease from the sick to the well is in private houses and in hospitals, yet, if this danger is thoroughly appreciated it is, for the most part, quite under control, through the immediate destruction of the sputum, and the enforcement of habits of cleanliness. But in places of public assembly, such as churches and theatres, particularly the latter, the conditions are different, and the safety would seem to depend largely upon a dilution and partial removal of the floating, and possibly dangerous, dust by means of adequate ventilation. Rooms in private houses and hospital wards that are occupied by phthisical patients should from time to time be thoroughly cleaned and disinfected, and this should always be done after they are vacated, before they are again occupied by other individuals. Steamship companies should be obliged to furnish separate apartments for consumptive persons, so that no person in the exigencies of travel need be forced to share his room with one who might be a source of active danger to him.

We desire to especially emphasize the following facts: 1st, That tuberculosis is a distinctly preventable disease; 2d, that it is not directly inherited; and 3d, that it is acquired by the direct transmission of the tubercle bacillus from the sick to the healthy, usually by means of the dried and pulverized sputum floating as dust in the air.

The measures, then, which are suggested for the prevention of the spread of tuberculosis are: 1st, The security of the public against tubercular meat and milk, attained by a system of rigid official inspection of cattle; 2d, the dissemination among the people of the knowledge that every tubercular person may be a source of actual danger to his associates if the discharges from the lungs are not immediately destroyed or rendered harmless; and 3d, the careful disinfection of rooms and hospital wards that are occupied, or have been occupied, by phthisical patients. Signed, HERMANN M. BIGGS, T. MITCHELL PRUDDEN, HENRY P. LOOMIS, Pathologists to the New York City Health Department.

Resolved, That Drs. T. M. Prudden, H. M. Biggs, and H. P. Loomis, the Pathologists of this Department, be and are hereby requested to formulate a brief and comprehensive statement regarding the contagiousness of tuberculosis in man, stating therein the evidence of the same, and recommending in the briefest possible manner practicable the simplest means of protection from its influence.

[1] A cheap and efficient cup answering this purpose is now on the market, and is supplied by the druggists.

A REMARKABLE INSTANCE OF FECUNDITY.—A woman in Edinburgh, Scotland, is pregnant at the age of sixty-two, it being her twenty-third time. She was also pregnant at the age of 47, 49, 51, 53, 56, and 60. The case is attracting much attention from the physicians of that place.—*Gaillard's Medical Journal.*

THE CZAR'S PHYSICIANS.—The health of the Czar is well looked after, if we may judge from the large staff of physicians and surgeons which is attached to the Russian court. The following comprises the list of the medical department: Three consulting physicians; ten honorary physicians; two surgeons, each of whom is paid; and three honorary surgeons; three accoucheurs, each of whom is paid; two ophthalmic surgeons; one physician for diseases of children; four practitioners for attendance upon the household, the posts of which are honorary; and lastly, one dentist.—*Medical Press and Circular.*

HEREDITARY PLUMBISM.—A detailed account of hereditary lead-poisoning in a baby has been brought forward by MM. Legrand and Winter. Both father and mother had been deeply poisoned. Five of their children had been born dead. The sixth lived only fifteen days. At the necropsy some remarkable signs were noticed. The kidneys were very small, weighing less than a drachm, granular, and sclerosed throughout. The liver showed universal circumlobular cirrhosis, with islands of fatty degeneration in the periphery of the lobules. Throughout this circumlobular fibrous tissue a solution of ammonium sulphide gave an abundant precipitate of fine black grains within the cells, which was slowly dissolved by acetic acid. The liver weighed nearly two ounces, and contained about three per cent. of lead.—*The Practitioner*, April, 1889.

THE FRENCH HOSPITAL.—The growth of the French Benevolent Society, which was founded in 1809 and incorporated in 1819, has afforded an interesting story of progress. At first a medical department was started, and the doctors visited among the French poor of the city. In 1883 a "hospice" was established in Fourteenth Street, which afforded a resting-place for the aged and infirm. This work grew rapidly and a hospital was developed. Funds were raised by French societies in different parts of the United States, and not long ago new quarters were obtained at No. 322 West Thirty-fourth Street. The hospital was enlarged from twenty-two to sixty beds, a pathological department was added, and the work was extended in every department. Efforts have been made to raise funds for a new operating-room and an outfit of surgical instruments, with some degree of success. Perhaps the Society will make a very good showing on the coming July 14th, the anniversary of the taking of the Bastile.

ANTIRABIC INOCULATIONS AN UNSCIENTIFIC METHOD IN THE PREVENTION OF HYDROPHOBIA.

BY JOSEPH DRZEWIECKI, M.D.,

ORDINARY PHYSICIAN IN THE UNIVERSITY CLINIC OF THE HOLY GHOST HOSPITAL, WARSAW, POLAND.

THE question as to the efficacy of Pasteur's method of prevention of hydrophobia has been subjected to considerable criticism, and from time to time voices of scientific men have been heard in opposition, the greatest objections coming from Frisch, Ullman, and Peter.

Although Pasteur replied to Frisch's objections, yet his answer was very feeble and unsatisfactory.

From Pasteur's whole defence the most characteristic argument is addressed to Professor Peter, *i.e.*, that he cannot dispute with incompetent persons, as Peter had never made experiments. The *France Méaicale*,[1] noticing this fact, remarked that with similar arguments it was difficult to convince anybody, and that now we live in a strange time when the chemist — experimentator and not the physician—categorically accuses the professor and clinicist as incompetent in justifying the therapeutic methods.

The only argument which Pasteur always states in favor of his method is the statistics of inoculations. However, as we shall show further on, it cannot be considered as scientific, and therefore it cannot be seriously treated.

The editor of the *Journal de Médecine de Paris* showed upon what a weak basis Pasteur supported his statistics, and if they were seriously treated we should receive a greater percentage of mortality.

The English Commission had personally inquired into 90 cases treated by M. Pasteur, but only 24 of these were said to have been bitten by undoubtedly rabid dogs, so that the 8 fatal in this number were far in excess of the usual proportion of fatalities in cases of bites of rabid dogs, viz., five per cent. The report had reckoned that of the 2,682 cases treated at the Pasteur Institute the mortality should have been 130 instead of 40; but it ought to have been stated that only 233 of the cases were found to have been bitten by rabid animals, which would have given a mortality of only 15 if untreated. M. Lutaud contended that the Pasteurian method had increased the mortality instead of diminishing it. Before its adoption the annual average mortality in France was 30. The actual mortality in France during 1886 was 42, of which 25 had been treated by Pasteur.[2]

As Pasteur defends his method by statistics, let us cite other statistics. Dr. Kishensky[3] states cases, selected from the archives of the Katharine Hospital in Moscow. The whole number of cases amounted to 693, and from this number, excluding cases bitten by other animals, 591 were bitten by mad dogs, and there died only 8, or 1.35 per cent. But the author asserts that in this manner statistics cannot be treated, because about many of the cases it was not known whether they had been bitten by rabid dogs, and therefore omits all such cases and gives only those about which there was no doubt of their having been bitten by unquestionably rabid dogs. Some of them remained in the hospital under medical observation during at least six weeks, but the greater part of them three months and longer.

According to these statistics it is shown that out of 307 persons bitten by unquestionably rabid dogs, 18 were bitten in the head, 90 in the hands, 25 in the feet, 170 in places covered with clothes, and 4 in places not indicated. Of 18 bitten in the head 4 died, or 22.2 per cent.; of 90 bitten in the hands, 2 died, or 2.2 per cent.; of 25 bitten in the feet, no death, and of 170 bitten through the clothes, 1 only died, or 0.59 per. cent. If we add to the deaths another, belonging to the 4 about whom it is not known where they were bitten, we have 8 deaths, or 2.6 per cent.

Out of 24 cases severely bitten by rabid wolves, 2 arrived at the hospital with the symptoms of hydrophobia; 5 were in the hospital only during six weeks, 4 of them were discharged in good health, and 1, very severely bitten, died of septicæmia. The remaining 17 cases were under observation during eight weeks. Of this number 11 were bitten in the head, 3 in the hands, and 3 in places not indicated; 5 of them died, showing a mortality of thirty per cent., but, according to Pasteur, it is eighty-two per cent. All those who died had extensive wounds on the head. The author concludes that a greater number of persons died from the bite of wolves than from that of dogs, because the wounds of the former are larger and more numerous. Of 18 cases bitten by rabid cats only 3 died. Of 17 cases bitten by rabid horses, 9 were in the hospital during three months, and none of them died of hydrophobia, but 1 died of erysipelas and another of septicæmia. Of 4 bitten by a rabid hog, none fell ill. To this number we must add 4 cases bitten by rabid men, 1 by a white bear, and 1 by a rabid squirrel. Thus of the whole number bitten by rabid animals—396—there died 18, or 4.52 per cent.

If we now consider that in Pasteur's statistics are included many cases improved,' and if to this we add the cases given by Professor Peter, of which one died, as Peter asserts, in consequence of the antirabic intensive inoculations, and another died from rabies two years and three months after the antirabic treatment, we arrive at the conviction that the Pasteurian method has no value.

In order to accept the method of preventive inoculations as valuable, it is necessary to prove that it prevents the development of hydrophobia in men. Pasteur only proved that his method prevents the development of rabies in dogs. Still, the experiments made in this direction by Dr. Frisch do not demonstrate the value of the inoculations, and Pasteur explains the unsuccessful results of Frisch by the fact that the latter transferred the experiments from dogs to rabbits.

But if it is erroneous to transfer the experiments from dogs to rabbits, it is still more so to transfer them to men, as Pasteur does. Until now he has not yet proved that the inoculations prevent hydrophobia in men. The whole series of fatal cases treated in his Institute prove just the contrary.

1. On April 1st of last year a soldier of the name of Marinot, inoculated at the Pasteur Institute, died from rabies at Val-de-Grace.

[1] July 7, 1888.
[2] Vide Lancet, July 30, 1887, p. 235.
[3] Vratch, Nos. 44 and 45, 1887.

[1] France Médicale and Union Médicale (January 6, 1887) published a letter of Dr. Ziegel, in which he writes that ten soldiers bitten by a dog, suspected to be mad, were sent for treatment to Pasteur. After their return to Wilna, they found the dog that had bitten them in a perfect state of health, and five months afterward the soldiers and the dog were quite well.

2. On May 16th a young man (Poulet), aged twenty, died at the Hôtel Dieu Hospital from rabies. He had been bitten by a mad dog on December 6, 1887, and was treated at the Pasteur Institute from December 8, 1887, to January 6, 1888.[1]

3. O—— died from rabies, bitten on April 23d, and inoculated from April 26th to May 12th last year.[2]

4. On August 8th a young man named Guers, aged twenty-two, died at the Necker Hospital at Paris from convulsive rabies. He had been bitten by a mad dog on July 13th, and was treated at the Pasteur Institute from the 16th.[3]

5. On June 20th a child (Bertin), eighteen months old, died from rabies at Gentilly (Seine). The child, who had been bitten on May 15th, was inoculated at the Pasteur Institute on the 17th, and the treatment was continued for twenty-four days. The first symptoms became manifest about the eighth day after the completion of the treatment by antirabic inoculations.[4]

6. On July 23d a man, aged twenty-eight, died of rabies at the Hôtel Dieu of St. Étienne. He had been bitten by a rabid cat on June 16th, and was treated at the Pasteur Institute from June 20th to July 7th.

7. A child, at Marseilles, thirty-one months old, who was bitten on May 9th by a rabid dog, and treated at the Pasteur Institute from May 14th to June 9th, died from rabies on June 23d.

8. An inhabitant of Chatenay, aged forty-four, who was bitten on March 25th by a rabid cat, and treated at the Pasteur Institute from March 26th to April 12th, died from rabies on July 30th.

9. Madame Sarazin, of Saint-Maurice, in Switzerland, aged forty-four, who was bitten on July 1st by a mad dog, and treated at the Pasteur Institute from the 4th of the same month, died from rabies at the Hôpital Broussais, in Paris, on August 4th.[5]

10. C. W. Dean described a fatal case in a boy, five years of age, bitten by a mad dog, who had been treated at the Pasteur Institute, and discharged as recovered.[6]

11. At a meeting of the Academy of Medicine in Paris, on January 4, 1888, Professor Peter communicated a case, observed by Dr. Miquel, concerning a certain Révaillac, twenty years of age, bitten by a dog considered mad by a veterinary surgeon; the dog was killed the next day. The place of the bite was cauterized, and forty-eight hours after the bite had taken place the patient came to the Pasteur Institute. During twelve days injections were made three times a day in the hypochondrium. On December 12, 1887, the patient commenced to feel a great pain in the place of the injections and not in the place of the bite. In a short time general debility followed. The next day he was apathetic and dejected, and four days afterward died with foam on his lips. The day before his death he had convulsions and difficulty in swallowing. Death followed six weeks from the day of the bite.

12. In the *Semaine Médicale*[7] Professor Peter, speaking about microbes and alkaloids, states that Berger died six months, and Sinardot died two years and three months, after injections at the Institute.

Here we have some of the successful results of the Pasteurian treatment, selected from the literature of last year.

Pasteur himself, knowing well the insufficiency of the inoculations, found it advisable to take a certain precaution, namely, that his method cures only such cases where the bite is not deep and not on the head. What is the good of such a precaution? Is it not evident that the inoculations help at that time when the virus has not entered into the blood, and are inefficacious if the virus has been introduced?

I cannot understand why Pasteur's method is unsuccessful in cases where bites by rabid animals are large and deep, especially in the face. If the virus acts through the nerves, the least scratch must allow the contact of the virus with the nerves, in which the skin abounds; at last the circulation permits the virus to come in contact with all tissues.

Every new method deserves our attention as long as it shows itself efficacious in serious cases which cannot be cured by other methods. Meanwhile, the Pasteurian method includes only slight and doubtful cases, and excludes the serious; in one word, it cures those cases which probably would recover without any inoculations.

Finally, Pasteur asserts that the inoculations weaken the virus introduced by the bite of a rabid animal, *i.e.*, accustom the organism to the virus, no matter whether the unfortunate persons treated by him have or not very violent symptoms of rabies. If the inoculations harden the organism against the virus, then the symptoms of rabies should be very mild, as it is evident in small-pox. In what way, I ask, does Pasteur see the preventive properties of the inoculations? His method neither prevents rabies nor does it weaken its symptoms.

If we consider the above, and add to it the cases given by Professor Peter, out of which the first died, probably from intensive inoculations, the second in six months, and the third died from rabies two years and three months after the Pasteurian treatment, we must acknowledge that this method can only be of value for veterinary surgeons, but being transferred to men, it is unscientific, and as such must be condemned in the interest of humanity and science.

I must still mention that the experiments made by Professor Roch, and M. Schutz, professor of the Veterinary School of Berlin, have shown that the mortality from charbon is sensibly the same in vaccinated and unvaccinated animals, and the practice has been nearly entirely abandoned; and, therefore, this Pasteurian method also, which made a great noise in the world and was accepted with enthusiasm, has been proved to be false.

A REPORT ON THE MINERAL WATERS OF THE UNITED STATES BY THE COMMITTEE APPOINTED BY THE AMERICAN CLIMATOLOGICAL ASSOCIATION.[1]

By CLARENCE C. RICE, M.D.,
NEW YORK.

At the Third Annual Meeting of the American Climatological Association, held in Philadelphia in May, 1886, it was recommended and approved that a committee be appointed to investigate the subject of the mineral waters of the United States. I was made chairman of this committee, and was given power to add two members of this Association to the committee.

I was fortunate in securing the services of Alfred L. Loomis, M.D., for your committee, as Dr. Loomis has always taken a deep interest in the study of the therapeutic value of our mineral springs.

In the President's address, delivered at the Second Annual Meeting, Dr. Loomis recommended that this Association should include the study of our mineral springs in its investigations, and prophesied a great future for the intelligent application of this department of therapeutics. Your committee was also much strengthened by the addition of J. L. Cabell, M.D., of the University of Virginia, who has a very thorough knowledge of the Mineral Springs of Virginia.

It was not the intention of this committee to compete in any way with the very valuable and painstaking work which has been accomplished by a member of this Asso-

[1] Read before the American Climatological Association at its Fifth Annual Meeting, September, 1888.

ciation, Dr. A. C. Peale, of the United States Geological Survey. Personally, I may say that I hope the Climatological Association will receive as much credit from his investigations as will the United States Geological Survey. The gentlemen are familiar with the paper read by Dr. Peale, "The Classification of American Mineral Waters." The present committee could not hope to add any further information as to the chemical analyses of the nearly eight hundred American springs which have been compiled and tabulated by Dr. Peale, and printed in Bulletin No. 32 of the United States Geological Survey. Nor has any attempt been made to increase the number of springs found in that list, which is the most complete one for reference. We find a number of springs in our report which we do not find in Dr. Peale's list, but it is probable that he has them under a slightly different name. And just here we would say that the work of studying our American mineral springs is considerably embarrassed by the constant repetition of names of springs even in the same State and county. In Virginia, Tennessee, Kentucky, and other Southern States, we have White Sulphur and Red Sulphur and Black Sulphur repeatedly used as names, and oftentimes with little else in the way of nomenclature to distinguish them. We hope eventually that springs which are found to be of therapeutic value will be named so that they will not be confounded with other springs. It is desirable that a nomenclature based upon the name of the owner of the spring, as Smith, Jones, West, etc., which is, of course, liable to frequent changes, or a nomenclature based upon a single chemical constituent, as alum, iron, or sulphur, be done away with. Perhaps there is no better method of nomenclature than to give the spring the name of the town in which it is situated, as is done with the Ems and Carlsbad, and distinguishing the various springs in the same town by a name indicating their principal chemical ingredient. It may come within the province of this Association to suggest appropriate names for springs which prove to be of value medicinally. It was thought that your committee could best serve this Association by endeavoring to make a therapeutic classification based upon the physiological action of the waters. Thus far all therapeutic deductions have been based upon the chemical composition of the spring. Such deductions must necessarily be liable to error, for several reasons. 1. The analyses are not trustworthy in many instances. 2. There are many so-called "indifferent" waters which contain no prominent mineral ingredient, so that it is not possible to even speculate as to their therapeutic effects. 3. While many analyses are accurate enough, our knowledge of the physiological effects of a combination of a dozen salts in varying proportions, viewed from a chemical stand-point, is, and probably always will be, very imperfect. At present therapeutic deductions are based on the assumption that the predominant mineral ingredient or quantity determines the physiological effect of the water, and we know that this does not always appear to be the case, for frequently the effects are totally different from what the ingredients alone would produce.

With the hope of obtaining some new data as to the physiological action of our mineral waters, we drafted the following letter of inquiry:

"*To the Proprietors and Resident Physicians of the Mineral Springs of the United States.*

"NEW YORK, May, 1887.

"The undersigned, having been appointed a committee by the American Climatological Association to investigate the subject of Mineral Springs with respect to their value as sanitary and therapeutical agents, respectfully solicit your co-operation and request you to answer as promptly as possible the following questions.

"1. The location and name of the mineral springs in which you are interested:

"2. The analysis of the waters, if any has been made by competent chemists. In furnishing a tabular statement of the quantitative analysis, please be careful to state the quantity of water represented, whether a pint, quart, or gallon. This is sometimes omitted and the table loses its value.

"3. What are the physiological effects of the water? That is to say, what effect has a definite quantity of the water on the natural functions of life, as indicated by the pulse, by any change in the quantity or quality of the secretions, by the appetite, by the general feelings, etc. Note any variations connected with differences in the amount of water taken.

"4. What are the diseases in the treatment of which the waters seem to exert a real therapeutical effect?

"5. What is your mode of using them in each of these classes of diseases, and with what results?

"6. At what season of the year are your observations made?

"7. What is the average number of people treated yearly?

"8. Is there a Signal Service station in your neighborhood? If so, can you furnish a copy of the reports for the last season of the springs? If not, has any record of temperature and relative humidity been kept by you or others? If so, please furnish a copy.

"GENERAL REMARKS.—Please add anything of interest relating to the subject of mineral-water therapeutics."

This was mailed to the address of every mineral spring in the United States given by Walton, and to each spring in Dr. Peale's classification which was mentioned as a resort, or where the waters are used commercially. Five hundred and eighty-three letters were sent out; answers were received from 308 mineral springs. The answers consisted not only of the committee's blanks, more or less filled, but every variety of hotel circulars and advertisements, printed descriptions of the town and springs, etc. Probably three-fourths of the answers were written by hotel proprietors. The names and locations were usually satisfactorily given. In regard to analysis, Question No. 2, I need say little, as that ground has been thoroughly covered by Dr. Peale, and we would refer anyone who desires to ascertain the chemical analysis of any spring to consult Bulletin No. 32 of the United States Geological Survey. Most of the analyses we have received were a number of years old. Many of them were given in a rough way and were qualitative, not quantitative.

We regret to say that our third question elicited little valuable or scientific information. The majority of the answers were written by the owners of the springs, probably because there was no physician who was especially identified with the use of the waters, and because the owner preferred to trust himself to give all the healing and curing properties of his water. Whenever the next investigation of our mineral springs is made, we would advise that the United States Medical Directory be consulted and the inquiries addressed to the reputable physician who resides at the springs. Our envelopes were addressed to the resident physician or hotel proprietor. We have received but few intelligent replies from physicians; most of the physicians, in their zeal to state the wonderful therapeutic powers of the waters they were interested in, have confounded physiological action with therapeutic effects. It is discouraging to endeavor to extract anything of value from a report of a mineral water in which all the functions of life are said to be affected, and that, too, in the most unphysiological manner.

Many of our answers would read as follows: "Our waters act on the skin, kidneys, and bowels, and are useful in liver, kidney, stomach, and bowel disorders, and in rheumatism." In arriving at therapeutic deductions, therefore, there is a strong temptation to consult the analysis table alone and base our opinion of the therapeutic value of the water on the known physiological action of the one or two main mineral ingredients, and this is proper up to a certain point, for we shall always be guided by the analysis in selecting the proper spring for our pa-

tients. Clinical investigation comes later, and must supplement our knowledge of the chemical composition of waters. It is encouraging, however, to note that much more attention is being paid to the investigation of mineral waters each year. The letters of inquiry which have been sent out will stimulate physicians, we believe, to treat their cases more satisfactorily, and will induce owners to furnish better accommodations for patients.

Dr. George B. Fowler, of New York, has also sent out a large number of letters of inquiry in regard to our mineral springs, the results of which have been published in Wood's "Reference Handbook of the Medical Sciences."

A committee of the American Medical Association, of which Dr. William Pepper [1] was chairman, made their report in June, 1880.

The report consists mainly of a classified list of all the reliable analyses. No attempt was made to tabulate the clinical effects of the waters.

Dr. J. R. Duggan, of Macon, Ga., in 1881 wrote a comprehensive account of the mineral springs of Georgia.

Our fifth question: "What is your mode of using the waters in each of the classes of diseases, and with what results?" was, with but a very few exceptions, ignored. The answers were seldom more explicit than "bathing and drinking." The answers did not explain the kind of bath or method of giving it, and no directions, except in a few instances, were given as to the quantity of water to be taken, or the proper time of using it.

Question 7, "What is the average number of people treated yearly?" was not answered fully enough to give us any adequate idea of the number of people in the United States who yearly drink the waters, or take the baths at our mineral springs. I have, however, placed the number received on my table.

In regard to Question 8—asking for a record of temperature, humidity, etc.—the few answers received make it evident that we cannot depend upon any private sources of information, but must consult Signal Service statistics.

I need not say to this Association that the matter of mean temperature at the location of a mineral spring, its relative humidity, the topography of the country, its general environment in the matter of scenery, hotel accommodation, society, etc., are all matters to be as carefully studied as the character of the waters, for it remains still to be proved that there are more cures recorded at those springs which contain an abundance of mineral matter than would be effected at a spring of remarkable purity containing a palatable quantity of carbonic-acid gas, as the Underwood Spring water, of Maine, and the Salutaris, of Michigan.

Many of the most striking therapeutic effects are seen at springs which contain but a few grains of mineral ingredients.

Macpherson [2] says: "The vast majority of sulphur or of chalybeate springs in England are so slightly impregnated with any mineral contents that the cures effected by them must be regarded simply as cold-water drinking cures."

And no one can deny that pure water can be prescribed in such a variety of ways as to produce many different physiological actions.

The following classification has been prepared in order to show both the physiological and therapeutical action of the mineral springs. It is impossible at this date to give to the Association the reports which have been heard from through our letters of inquiry. It will require a longer time to obtain reliable information from many of our watering-places.

Name of spring.	Location.	Source of information.	Number of people treated yearly.	Method of using waters.	Situation near Signal Service Station.	Analysis, scientific or rough.	Chemical classification.	Physiological action.	Therapeutic effect in diseases of—						Therapeutics of external use of waters.
									Digestive system.	Respiratory system.	Genito-urinary system.	Nervous system.	The skin.	General diseases.	

How can the American Climatological Association encourage the physicians who practise at our mineral springs to make careful clinical observations in their work, and to keep honest records of their cases? If this Association desires to be responsible for this work, a systematic plan must be elaborated—a committee must be formed composed of one, perhaps two members from each State. The committee should print letters of inquiry and record blanks, covering not only physiological action and clinical observation, but they should also include the Signal Service reports as to temperature, humidity, rainfall, sunshine, etc.

These record blanks should be as simple as possible, so that they could be filled out with the least possible trouble. The resident physician of the largest experience should be addressed by the member of the committee from his State, and he should be requested to make monthly reports during the "season." I presume most resident physicians

[2] Macpherson: Baths and Wells of Europe, p. 108.

would comply readily with such a request. The hope of the proper recognition of the therapeutic value of the mineral spring would be a sufficient reward to the resident physician, and such recognition would increase his reputation and income. The Association needs also to look after the matter of the chemical analysis of American mineral waters. About nine-tenths of the entire number remain unanalyzed, and the analyses of the remaining one-tenth are, many of them, old and worthless, as it is known that the chemical composition of many of the waters is constantly changing, new salts being formed by the interchange of acids and gases.

It would be well perhaps for this Association to adopt some one of the many schemes of chemical classification which are now in use.

The simplest one, which at the same time covers the ground in a comprehensive manner, is the most desirable. From a chemical stand-point Peale's classification seems to be the most correct, and preferable to Walton's, for the reasons stated in his paper of last year. His four main groups—1st, alkaline; 2d, alkaline-saline; 3d, saline; 4th, acid—will be sufficient for the ordinary practitioner of medicine, while the number of subdivisions may be utilized by the chemist or medical expert. A still simpler classification may be found in Wood's "Reference Handbook of the Medical Sciences," vol. iv., p. 690, in which there are also four groups: 1st, Neutral, containing the chlorides and sulphates, 2d, alkaline, the carbonates; 3d, acid; and in the fourth group are included waters which contain unusual ingredients. There is the same objection to this last group as could be urged against the older one which was headed "Indifferent Waters." No two persons are agreed either as to what is an indifferent water or one in which the ingredients are remarkable. In comparing American springs with those of Europe, our lack of thermal waters, north and east, is always noted to our disadvantage. It is for this Association to determine whether our waters, artificially heated, are not therapeutically just as efficient as natural thermal waters of the same chemical ingredients.

In many of the replies received, the owners of the springs indicated a wish to have the waters analyzed. They apparently do not know how to secure an analysis. The United States Government is, I understand, quite willing to analyze any waters. The government management of many of the European waters has largely developed their resources. It would be a step in the right direction if this Association could secure such legislation as would compel the analysis of all mineral waters which are used medicinally.

J. L. CABELL, M.D.,
CLARENCE C. RICE, M.D.,
Committee.

FLUTE-PLAYER'S CRAMP.—A case of professional cramp in a flute-player was well described by M. Féré at a recent meeting of the Société de Biologie. The patient was a habitual member of a theatrical company, to whom the flute was the only instrument allotted. He felt at first a paralysis in the extensors of the ring-finger and little finger of each hand, and then a cramp in the opposing muscles, which made him drop the instrument, sometimes with a cry of pain. Local massage and general tonic treatment brought him back again to a condition fit to resume his former work, though those of his audience with a finer ear than the rest could trace the effects of the cramp in the slightly slower time in which the notes played by the ring-finger and little finger were given. M. Brown-Séquard took the opportunity to press the remark that in such cases of professional cramp the fatigue of the whole body was at least an equally essentially component with the local strain. In a case of writer's cramp in a Cincinnati journalist he had seen both feet as much affected as both hands after an excess of writing.—*The Practitioner.*

RICKETS—ITS PREVALENCE IN BUFFALO, AND ITS PROBABLE INFLUENCE UPON THE DEATH-RATE AMONG YOUNG CHILDREN.[1]

BY IRVING M. SNOW, M.D.,
BUFFALO, N. Y.

DURING my stay in Europe I was struck with the frequency of rachitis in the large cities, and with the important rôle it seemed to play in most of the diseases of young children. In the clinics of Monti and Widerhofer in Vienna, as a case of bronchitis, pneumonia, or diarrhœa came up for examination, the professor would often lay great stress upon the fact that the pulmonary or intestinal disorder was complicated with rickets, and that all correct therapeutical measures must be addressed to the underlying cause as well as to the more prominent symptoms. That rickets is exceedingly common throughout all Europe is shown by the statistics of various authorities. Gee found that thirty per cent. of all children under two years of age admitted into the Great Ormond Street Hospital, London, were rachitic; Ritterhain, in Prague, estimated the percentage of rickety children in the hospital at thirty-one; in Manchester the proportion of rickety children applying for treatment at dispensaries and hospital was thirty per cent. of the whole number. In Vienna and Berlin the percentage is certainly no less. Sir William Jenner, in his classical lectures upon rachitis, says: "Of the tubercular, the rachitic, and the syphilic diatheses, the rachitic is the most frequent, most fatal, and the most important." Of American authors Jacobi and Parry alone assert that rachitis is common in the United States, and most American physicians believe it to be a disorder of the Old World, not often present in American children. Most of the younger members of the profession have, I think, shared in this opinion, influenced by the stand-point of prominent authors and by the slight emphasis laid upon the disease by their clinical teachers. It is quite possible that in former years rickets was rare in this country, but times have changed, and the conditions of life are no longer the same as thirty or forty years ago. The population of the large cities has enormously increased, and is different in character. The number of families in easy circumstances has greatly multiplied, and wealth, bringing with it many advantages, also carries with it the disadvantage that many mothers are now unable to nurse their offspring. Again, the proportion of families either in indigent circumstances or who at least are obliged to exercise severe economy is very large. Many of our citizens are of foreign birth or parentage, of peasant stock, who have settled in large towns. Thus their children no longer have the advantages of air and exercise which the parents enjoyed; thus finding virtually the same conditions of life for children prevailing in American and in European communities, viz., city environments and artificial diet. I have made some slight investigations as to the prevalence of rachitis in Buffalo.

Etiology.—Rickets is largely confined to children reared upon artificial food; its heredity is questionable. Thus Trousseau found that among one hundred rachitic children ninety-eight had either not been suckled at all or had been weaned very young. Uncleanliness, want of sunlight, bad air, and insufficient clothing are also important factors in its causation. Nevertheless, children reared under the most favorable hygienic surroundings will become rachitic if improperly nourished. I will quote the remarks of Dr. Cheadle upon this subject. He says: "In the development of rickets it is the quality and not the quantity of food involved. The defect in most artificial foods is in the excess of their starchy elements. Not that starch is itself injurious, although difficult to digest and prone to fermentative changes, but to the absence of other ingredients, deficiency in fat and animal proteids.

[1] Read before the Alumni Association of the University of Buffalo, Medical Department, March 26, 1889.

The correct proportion of fat to the solids in human milk is 1 to 4; but many artificial farinaceous foods contain a mere trace of fat—from $\frac{1}{20}$ to $\frac{1}{100}$ of the total solids. Rickets is, according to Cheadle, a diet-disease, which may be caused at will by rachitic diet and cured by anti-rachitic diet.

A child will inevitably become rachitic if its food is lacking in animal fat, in earthy salts, or in animal proteids. Further, in rickety children the disease is intensified by foul air and want of sunlight, and is also modified by syphilis and scurvy. Dr. Cheadle relates an interesting chapter in comparative pathology. In London it has hitherto been impossible to rear the numerous litters of young lions born in the Zoological Garden. Some twenty litters perished in succession last year. An examination showed that all of the cubs died of acute rachitis, as shown by the condition of the bones. It appears that lionesses in captivity do not suckle their young, as they are apt to injure or neglect them. The young cubs are therefore fed upon the flesh of old horses. This meat, as will be readily imagined, is very tough and very lean, and the bones are so hard that the powerful jaws of an adult lion are unable to crack them. Thus the young lions are unable to get the earthy salts and nutritious fats contained in the medullary cavities. Mr. Sutton put the young lions upon chopped meat, pounded bones, and cod-liver oil, and, greatly to the surprise and joy of his colleague, succeeded in raising a litter, an event almost unprecedented in the traditions of the Zoological Garden. Rachitis is now regarded as a general disease, involving all important tissues of the body.

This is demonstrated in the blood by the pallor of rachitic children; in the skin by excessive sweating; in the nervous system by various phenomena, as convulsions and tetany; in the muscles by the languor and weakness of rickety children; in the mucous membranes by the tendency to croup, bronchitis, and diarrhœa; in the ligaments by the yielding of the spine and by relaxed knee and ankle joints; in the osseous system by the bending and deformity of various long bones, by enlarged epiphyses. I am unable, for lack of time, to go deeply into the pathology and morbid anatomy of rachitis. The changes in the bones are most striking and have been very completely studied. There is increased absorption of osseous tissue, accompanied by the formation of an osteoid tissue incompletely calcified. The proliferation of cartilage-cells is increased, and the continuous absorption of bony tissue has the effect of enlarging and multiplying the medullary cavities. Rachitic bones are soft, easily bent, may be cut by a knife, and are hyperæmic. The process heals by osteo-sclerosis, the bones becoming very hard and dense. I will say, in passing, that it is remarkable to see what extreme degrees of deformity of the thorax and extremities will disappear under proper treatment.

Symptoms.—All physicians are familiar with the extreme types of deformity found in rachitic children. It is undoubtedly true that pigeon-breasted children and children with crooked legs are somewhat rare in America, and, since the idea is common that rickets is a disease necessarily accompanied by extreme deformity, the conclusion is reached that rickets is one of the rarer diseases of children. On the contrary, rachitis is often most insidious in its appearance, and in the early stages can be detected only by a careful physical examination. Well-authenticated cases of fœtal rickets have been reported, also cases beginning after the third year; but it is my purpose in this paper to dwell only on common types, to discuss its prevalence in Buffalo, to consider its probable influence upon the mortality among children, using the vital statistics of Buffalo as my text.

I will briefly rehearse the most prominent symptoms of rickets, omitting contested points: (1) Rickets may show itself in young children, from two to four months of age, by obstinate constipation, requiring laxatives and injections to overcome. At this stage the child may be fat and apparently quite well, except that it is pale and languid. The mother may also say that the child is very restless, kicking off the bed-clothes at night, so that even in a cold night she will find it uncovered. Occasionally these children are very tender to handle, crying as if in pain when they are carried or caressed. As the disease progresses, changes are apparent in the skeleton. You will often see a child whose mother considers it a marvel of beauty and plumpness. She will point to the wrist and ankles, where the child appears to be so fat that the joint looks as though it were tightly constricted. It will commonly be found that this bulging at the wrist is due to swelling of the epiphyses, and that the bony structures at the wrist and ankle are largely increased in size. The same enlargement may take place at the knee and elbow. Changes also occur in the skull; absorption of osseous tissue, which is an essential feature of rachitis, takes place in the occipital and parietal bones. This softening, called cranio-tabes, is principally found in the occipital bone, about the lambdoidal suture; it may be discovered by carefully palpating the back of the head. Cranio-tabes may be so far advanced that only a membranous covering protects the brain from external pressure. The head is usually square in contour, and the anterior fontanelle, which should be completely closed at the fifteenth to the eighteenth month, may remain open as late as the third year. The jaw, instead of having an oval contour, is somewhat squarely shaped in rickets. In fact, the irregular shape of the inferior maxilla may greatly embarrass dentition. Dentition is late and irregular, and will be more fully discussed in another portion of the paper. Most conspicuous are the changes in the thorax. These are very frequent, and have a most important effect upon the health of the child. First, there may be a beading of the ribs, the so-called rachitic rosary. This condition may vary from a slight elevation at the junction of the rib and cartilage to a well-defined series of nodes on either side of the sternum; generally, the rib is depressed, and the rachitic swelling is larger in the chest than it seems outside. If the disease progress, the sternum is pushed outward, with a distinct groove on either side. The chest is narrowed laterally, and we have the classical pigeon breast. A lateral spreading of the thorax in the region of the floating ribs may take place. Here the softened ribs are pressed outward by the liver, spleen, and flatulent stomach and intestines. The chest appears to be transversely constricted. The lungs of rachitic children are small and often emphysematous, there being an absolute diminution in the capacity of the thorax. There may also exist a posterior curvature of the spine. This deformity is, however, merely an exaggeration of what may be seen in every infant when placed unsupported in a sitting position, and be due to softening of the bodies of the vertebræ, to stretching of the ligaments, and to muscular weakness. By holding the child up, with the hands in the child's axillæ, this curvature will always disappear. I will leave to obstetricians the description of the malformations of the pelvis. They are caused by softening of bone and pressure, and are fraught with misery to the parturient woman and woe to her offspring. Various twists and deformities occur in the extremities—bow-legs, genu valgum, and curves in the femur and humerus. Associated with the symptoms I have just enumerated is often an enlarged spleen or liver. It is, however, doubtful whether enlargement of these organs is anything more than a complication. The amount of muscular debility is far in excess of any wasting which may occur; in fact, a tubercular child, considerably emaciated, will display far more strength than a rachitic child apparently fairly nourished. There is evidently a profound disturbance of innervation in rachitis. Most authors speak of an increase in the salts of lime in the urine, while Jacobi asserts that they are diminished.

I wish here to emphasize the fact that all of these symptoms are not present in every case of rickets; an association of two or three is sufficient to establish a diagnosis. Although rickets is essentially a chronic disease, lasting

months or years, it may at any time be favorably influenced by diet. Even under a proper regimen, from six to twelve months are required for a cure. Rachitic children are late in walking; are mentally backward; are liable to attacks of dyspepsia, diarrhœa, spasm of the glottis, convulsions, and bronchitis. They succumb easily to any acute disease, or to any intestinal or pulmonary trouble. The feeble vitality of a rachitic child should be always a weighty factor in prognosis and treatment. I have postponed any enumeration of my cases of rachitis until now, wishing first to review the symptoms and etiology of the disease. During the last three months I have personally seen and examined 25 children with rachitis. Of these, 2 were seen in private practice. Of 25 children under three years of age seen at the Fitch Dispensary, 10 presented well-marked symptoms of rickets. I also examined 33 children under three years, in two orphan asylums, of whom 13 were rachitic. Therefore, of 58 children seen in various ways 23, or about forty per cent., showed well-defined symptoms of rickets. These children were either bottle-fed, or, if suckled by the mother, were given in addition various starchy foods. The diagnosis was always based upon an association of the following symptoms: Delayed dentition, open fontanelle after the age of eighteen months, beading of ribs and thoracic deformity, swelling of the epiphyses, and bending or deformity of the long bones. Delayed dentition and beading of the ribs were almost always present. It is noteworthy that, with three exceptions, all of the children were of foreign parentage—usually Irish, German, and Polish, 3 being of Italian and 1 of African descent. Most of them had suffered from repeated attacks of bronchitis and diarrhœa. All of them were backward in walking, of capricious appetite, and poor digestion. One rachitic child suffered from a large intramuscular abscess; another had a remarkable enlargement of the spleen, with œdema of the extremities, fever, and intense anæmia. Some had had slight convulsive seizures. Two cases were in one family, being the youngest of a family of five, illustrating the observation of Jenner, who says that rickets, in contrast to syphilis, shows itself in the youngest children, each successive child being more subject to rachitis than its predecessor. An explanation of this is that in poor families the mother is exhausted with child-bearing and household cares, and each additional child diminishes the resources of the family. Thus the child comes from enfeebled stock, is neglected, and often poorly nourished. Another child was in apparently blooming health. It was suckled by the mother. Nevertheless this baby, eight months old, presented well-marked beading of the ribs, and the wrist- and ankle-joints were considerably enlarged. By close questioning I elicited the fact that it suffered from frequent attacks of colic, and that its stools were masses of undigested milk. I very much regret that I am unable to present a larger number of cases than 25. But it seems to me apparent that these 25 cases, gathered from several different sources, must represent in some degree the prevalence of the disease in this city, for forty per cent. of the cases seen in the dispensary, and forty per cent. in the asylums, is too large a proportion to be the result of accident. I therefore believe the disease is very common in this city. If rickets prevail to any extent in American communities, it must exercise a very important influence in all diseases of childhood, and must play an exceedingly important rôle in infant-mortality. As dentition is almost always retarded and irregular in rickets, I may be permitted to dwell at some length upon its pathology. It is a stormy epoch with children. Although a physiological process, which should be regular in its course and without danger to life, nevertheless all authors agree that any illness occurring during teething is aggravated in type and dangerous and protracted in course. Convulsions, diarrhœa, bronchitis, are common in these critical months, and the mortality among children from six to twenty-four months of age, in Buffalo, is 1,500 yearly. I even find dentition ranked as a cause of death, 16 deaths from dentition being returned. Yet teething goes smoothly on in healthy children, the central incisors appearing at the seventh month, the lateral at the ninth, the first molars at the twelfth, the canine at the eighteenth, and the second molars at the twenty-fourth month. Any essential deviation from this order is a variation from the standard of health, and its cause should be sought for and explained. Delayed dentition is not due to all causes which enfeeble a child, for in infants suffering from diarrhœa or tuberculosis the eruption of the teeth is regular, and the teeth are often well formed and strong. Among the laity, many maladies of childhood are referred to the malignant influence of teething, and mothers ask their physicians why their children are so fretful and sickly, and why the teeth do not appear at the appointed time. The maternal anxieties are usually quieted with soothing assurances that all will be well in time, but the most common cause of irregular or delayed dentition is rickets. A rickety child may have no teeth even as late as the second year, or the eruption of teeth may progress regularly until the incisor teeth are through, and the child becoming rickety, dentition may be arrested for months. These rachitic teeth are very prone to decay, and most physicians have observed how very bad the teeth are among the children of the city poor. No physical examination of a sick child is complete without a careful inquiry into the condition of the teeth. If dentition be late or irregular, and if the child be harassed by digestive troubles, or obstinate pulmonary catarrh, the underlying cause will almost invariably be found to be rickets. I will quote again from Sir William Jenner upon this subject:

"If a child pass over the ninth month without teeth, you should carefully inquire for the cause. It may be that an acute illness has retarded dentition. It may be, but this is very rare, that there is some condition of the jaw which interferes with the advance of the teeth; it may be, and this is infinitely the more common cause of late dentition, that the child is rickety. Fail not, then, when called to a child in whom the teeth are late in appearing, to look if it be rickety, for if you fail to look for rickets you will most likely attribute to the irritation of teething symptoms which are the consequence of the rickety diathesis, the late dentition of rickets being in itself a symptom of the general disorder. The rickety deformities may be very trifling, and yet the teeth be considerably retarded in their development."

Digestive troubles in rickets.—One of the most prominent of the early symptoms of rickets is constipation. In a fat and well-nourished child two and three days may pass without an evacuation from the bowels. This constipation may precede the enlargement of the epiphyses and is present between the second and fourth month. Rachitic children are, in fact, constant sufferers from indigestion. They alternate between constipation and diarrhœa, and their stools present a great variety of color and consistency. Almost constant flatulence and colic are present. Rickets may also appear after a severe attack of cholera infantum or entero-colitis; the child ceases to walk; dentition, heretofore normal, becomes arrested, and the characteristic beading of the ribs is seen. Last year there died in this city, of digestive troubles, 567 children under the age of three. Of these, 403 died of cholera infantum, 132 of diarrhœa, and 32 of dysentery. It is well known that children suckled at the breast usually escape these serious illnesses, and if attacked are not apt to die; and also that children affected with cholera infantum are usually hand-fed and badly nourished upon cows' milk diluted with water, or upon artificial foods. These diseases prevail among children who have suffered from digestive troubles, amid a high temperature and vitiated air. I have examined many children with dyspepsia and diarrhœa in Vienna and London, and have found them rachitic in a very large portion. It is my firm conviction that if children who die of diarrhœal troubles were carefully examined the underlying cause of the enfeebled vitality and tendency to alimentary troubles would be found to be rickets. Surely the subject is worthy of investigation,

offering, perhaps, an explanation of the prevalence of those diseases which yearly decimate the infant population.

Bronchitis and pneumonia.—I will next consider the respiratory disorders of young children, seeking some explanation of the excessive death-rate, among patients under three years of age, from bronchitis and pneumonia. In 1888, among children under three years of age, there died 94 from bronchitis and 187 from pneumonia, a total of 281. It is probable that most of the cases returned as pneumonia were catarrhal or broncho-pneumonia, pure lobar pneumonia being rare among young children. Many of these fatal cases were undoubtedly secondary to measles, whooping-cough, or diarrhœa. Inflammations of the respiratory tract are exceedingly dangerous to infants in this climate, and it is instructive to study the various predisposing causes, the type of the disease, and the age and evironments of the little ones who succumb to bronchitis or pneumonia. Very hopeful is the prognosis in a healthy child who has been suckled by a strong and sensible mother, who has had the advantages of good air, sunlight, and proper diet. A physician attending two cases of lobular pneumonia will see one die and the other recover under the same treatment and the same conditions. He will account for this by considering that the dead child was a "bottle baby," that its vital forces were not equal to its more fortunate companion; in short, that it had a feeble constitution. Yet the feeble constitution may not be traceable to the mother, who is often strong and robust. Nevertheless the child was harassed by dyspepsia, was backward in teething, and fretful and feeble. Young children do not expectorate; the inflammatory products are coughed up and swallowed. Any condition which en feebles the muscular tissue of the lungs or the accessary muscles of respiration materially increases the danger in catarrhal pneumonia. This is also true of any malformation of the thorax which may diminish the number of air-cells available for respiration. Children do not die from high temperature in bronchitis, but from asphyxia, and two clinical features present themselves in dangerous cases: 1. A child with very rapid respiration (100 to 120), a feeble and quick pulse, a fairly high temperature (102° to 103° F.), râles throughout the lungs, sometimes with scattered areas of dulness, and often no perceptible alteration of percussion. The face is livid or gray, there is recession at the sternum during inspiration, and a perceptible impulse at the epigastrium.

2. In a child suffering from bronchitis or broncho-pneumonia the disease may present a peculiar and a typical course, the râles and dulness shift their location from day to day, and there may be only slight dulness with distant respiratory sounds. Occasionally bronchial or roughened breathing may be heard, and no râles at all. Vocal fremitus may be slightly increased. There is evidently no increase in the pulmonary inflammation, for there is no fever, the temperature being even subnormal. Nevertheless the child seems in imminent danger, there is great dyspnœa, rapid respiration, and a gray complexion. The patient may be half-comatose, gasping for air. This condition is caused by collapse of the lung, a frequent cause of death in infantile pneumonia. Pathologically, it may be distinguished from pneumonia by the fact that there is no accompanying pleuritis, that although foci of induration are scattered through the lungs they disappear upon inflation, and that these indurations, when incised, present a smooth surface like muscle, unlike the rough and granular tissue of pneumonia. Collapse of the lung will be found to be present in almost every fatal case of bronchitis or catarrhal pneumonia under twelve to eighteen months. The cause is often mechanical, the bronchioles being plugged by mucus which the child cannot cough up. The residual air in the alveolus is quickly absorbed into the blood, and the tract of lung is rendered completely airless.

Thus the plugging of the smaller tube is caused by muscular debility, greatly favored by a softened and flexible condition of the ribs and by thoracic deformity. But what causes this lessened vitality, this feeble constitution, from which a child dies suffocated by its own secretions? It is without doubt due to rickets more or less advanced, often unrecognized. If these children be carefully examined there will be found beading of the ribs, slight deformity of the thorax, large wrist-joints, delayed dentition, and great muscular debility. No more unfavorable condition to resist a pulmonary inflammation, either primary or secondary, exists than that presented by a rachitic child. The ribs are soft, the thorax deformed, the actual capacity of the chest is diminished, the spleen and liver are thrust downward in the abdominal cavity, the intestines are distended with gas, hindering the diaphragm in its descent; add to this disordered digestion and great muscular weakness, and it is no wonder that rachitic children die from pulmonary disorders. Fagge says: "It is a point of great practical importance to remember, that when one is called to a case of croup or broncho-pneumonia, one often has to do with an advanced case of rickets, although the mother may have thought the child in fairly good health at the beginning of its acute illness." Gerhardt ranks rickets as one of the most frequent predisposing causes of catarrhal pneumonia and alludes to the gravity of the prognosis in rickety children, from the deformed thorax and tendency to pulmonary collapse. Rilliet and Barthez allude to the sinister influence of rickets upon catarrhal pneumonia, accompanied as it is by grave disturbances of nutrition and by chronic diarrhœa. Angel Money says "rickety children are especially liable to bronchitis or broncho-pneumonia, speaks of the danger of pulmonary collapse, and says collapse of the lung is the result of bronchial catarrh, and that any catarrh, whether simple or from measles or whooping-cough, may be its cause, but the actual factor in its causation is deficient innervation, viz., rickets.

Sir William Jenner speaks of the great liability of rickety children to bronchitis and pneumonia, with attendant collapse of the lung. He mentions the enormous mortality among them from whooping-cough and measles, and asserts that rachitis causes, primarily and secondarily, more deaths than any other disease of childhood. It must also be remembered that a previously healthy child which has rallied from an acute illness may, in consequence of the profound disturbance in its nutrition, become rachitic, as shown by its inability to walk, arrested dentition, etc. I therefore believe that as rickets is common in this city, a large proportion of the deaths from pulmonary disorders are directly or indirectly due to its presence. I will lastly consider the influence of rickets upon the nervous disorders of childhood, first discussing a neurosis called tetany. This is a functional nervous disorder of rachitic children, and is called idiopathic contracture, carpo-pedal spasms, or, in modern nomenclature, tetany. A child suffering from dyspepsia, diarrhœa, or difficult dentition will often exhibit curious motor disturbances. The hands will be tightly clinched, and the toes are firmly flexed against the soles. This contracture is extremely painful, and is often overcome only by force. It may be produced or intensified by pressure over the large nerves or blood-vessels. The contracture of the extremities is usually bilateral, and may be paroxysmal, relaxing, or persisting for hours. Other regions may be attacked; the rigidity and contraction may affect the knee, elbow, and even the neck. In tetany the muscles are tightly contracted, and there may be œdema about the joints. Tetany is occasionally associated with spasm of the glottis and even eclampsia, both frequent symptoms of the rickety diathesis. The disease, in itself, is not dangerous to life, but, owing to its convulsive character, may be confused with cerebro-spinal meningitis.

I find that in this city there died last year, of convulsions, 241 children under three years of age. Exactly of what malady these children die is difficult to say, as a convulsion is merely a symptom of many diseases. The tendency to convulsions in children under one year of

age is very great, 212 of the deaths being in this period of life. The liability of infants to eclampsia is due to structural incompleteness of the cerebro-spinal system, the inhibitory centres being undeveloped, while the lower centres are structurally complete. Hence eclampsia in infants may be excited by a variety of trivial causes—indigestion, fright, febrile attacks, and a host of acute infections or inflammatory disorders. A convulsion may be defined as a tonic followed by a clonic spasm, and is the result of a discharge of the cerebral cortex. Victor Horsley has shown that there is no essential difference between infantile eclampsia, epilepsy, and epileptiform convulsions, etc. I will now briefly take up the various morbid processes accompanied by eclampsia, to see if the many deaths reported from convulsions may be traceable to well-defined disorders. Convulsions in the newly born are quite rare and are due to meningeal hemorrhage or asphyxia. They occur usually between the ages of four and eighteen months, the tendency to convulsions or convulsive symptoms diminishing with great rapidity after that time. Tubercular meningitis is very rare in the first year of life. Cerebro-spinal meningitis is an infrequent disease, and its symptoms are well known and evidently returned under a proper title. Neoplasms, apoplexy, and hydrocephalus are rareties in the first year of life, and hydrocephalus is certainly easily recognized. Meigs and Pepper, in reviewing the causes of convulsions, state that of 70 cases of sympathetic convulsions the disease present in 12 was scarlatina, in 9 whooping-cough, in 13 indigestion. Pneumonia, bronchitis, and cholera infantum each caused 3, fever of simple angina 6, dysentery 4, measles and dentition each 6, etc. With the exception of indigestion and dentition, which are vague terms, all of these diseases are easily diagnosed; their cause is evident by well-marked symptoms, and patients dying from these diseases are probably returned under their proper title. Yet Meigs and Pepper state that of the 1,316 children who died in Philadelphia of convulsions a large number should have been returned under other titles, as many of them must have been a mere result of organic disease of the cerebro-spinal axis or of other local or general diseases. Yet the same confusion or ignorance which prevails in Buffalo and in Philadelphia exists also in Breslau and in London, in the midst of famous seats of medical learning. In Breslau, of 8,884 deaths under one year, 2,466, or thirty per cent., were returned as being the result of convulsions. The same proportion, thirty per cent., is found in the London statistics. I am therefore forced to the conviction that most of the physicians returning deaths under the title of convulsions had sufficient knowledge to diagnose and to exclude meningitis and diseases with convulsive symptoms, and that we must search for some other cause for the large mortality from convulsions. I have shown that rachitis is common in this city, and is, I believe, usually undiscovered; and holding, as I do, to its frequency, I assert that many of the deaths ascribed to eclampsia were due to rachitis. As this theory may seem somewhat startling, I will cite evidence in support of my statement.

Gee, a distinguished physician of St. Bartholomew's Hospital, London, cites 73 cases of convulsions. Of these 56 were dependent upon the general condition of the child, no acute inflammatory or infectious disease being present. These 56 cases were therefore essential convulsions, and in each child he found evidence of rickets. He says: "A child may be attacked by convulsions while in apparently good health; but we must bear in mind that active rickets and the presence of a large amount of fat are by no means incompatible." It must be remembered that convulsions come on in weakly children from causes inadequate to produce eclampsia in healthy infants, viz., indigestion, the eruption of teeth, heat, cold, fright. Angel Money, in his new book, says: "By far the most potent cause of convulsions in children is rickets. There is an excessive activity of the centres of the brain and cord, upon which reflex spasm and convulsions depend. Convulsions may occur without assignable cause in rickety children, and it is of great utility in the treatment of convulsions in rickety children to know the cause." Henoch, of Berlin, says: "In all cases of convulsions I recommend the examination of the bones of the child. My experience is that infinitely the most frequent cause of eclampsia is rickets, and, taught by numerous cases, I examine in every eclamptic child the epiphyses, the thorax, and the head. In eclampsia, rachitis plays a more important rôle than dentition. We seldom see convulsions in teething children who are not rachitic." He is of the same opinion as to the etiology of laryngismus stridulus, or spasm of the glottis, which is a pure neurosis unaccompanied by structural tissue-changes in the larynx. Jenner had never seen but one case of laryngismus stridulus which was not dependent upon rachitis. Gee, Gowers, and Money all corroborate the idea that rachitic children are the ones who suffer from spasm of the glottis. This is additional testimony to the abnormal excitability of the nervous system in rickets. We must also remember that spasm of the glottis is an occasional cause of death. Parry, an American author, believes that both in private and hospital practice rickets and eclampsia are associated, but does not lay the stress upon the association that Gee does, finding a connection in only twenty-five per cent.

Elsässer attributes eclampsia in rickets to cranio-tabes. The convulsions usually come on when the child is in bed; the pressure of the pillow irritates the cortex, which is unprotected by its unyielding bone covering. Of 29 cases of soft occiput 14 had convulsions, 10 ending fatally. Vogel and Wellshire also speak of the gravity of convulsions in rachitic children, and believe that many children die, no changes being found in the brain or meninges. Yet Meigs and Pepper hold that rachitis is rare in America, and further say that the eclampsia in teething children is rarely serious; the 1,316 unexplained deaths in Philadelphia to the contrary notwithstanding. There is, happily, little difference of opinion in the treatment of rickets. Being essentially a disease caused by improper feeding and malnutrition, it is cured rather by dietetics than by drugs. It goes without saying that children are immensely benefited by fresh, pure air and sunlight, and that a removal to the country or seaside has a distinctly curative effect. This is also true of hydrotherapeutics, bathing the child with lukewarm or cold water, to which may be added a little sea-salt. Feeble children should be bathed before an open fire, and well rubbed afterward. Suitable clothing should be insisted upon, for it is astonishing how many layers of garments an unfortunate child with bronchitis will wear. Children should be regularly fed or suckled. A great evil is giving a child the breast whenever it cries, practically amounting to nursing it all the time. It is exceedingly common for children of a year to be brought to the table and share with the rest. The child is thus regaled with tea, coffee, vegetables, fruits, and pastry, and becomes so sickly and fretful that the house is filled with its lamentations from morning until night. Although starchy foods can be assimilated to some degree by a child of a year, yet farinaceous foods are prone to ferment, and are often given in such quantities as to replace the nitrogeneous and fatty elements so necessary to nutrition.

The same might be said of artificial foods which contain a lage amount of dextrine, a fair quantity of albuminoids, and relatively little fat. The proportion of fat to the solid constituents of milk should be as one to four.

Dr. Cheadle believes that the administration of peptonized food is injurious, weakening the functions of the stomach. Theoretically it might seem as if the salts of lime might be curative, as the bones in rickets are deficient in lime salts. However, bone already calcified is decalcified, as shown in cranio-tabes. There is often no lack of lime in the blood, as the urine—a secretion of the blood—often contains six times its usual per cent. of lime salts. Lastly, if lime salts be given, they only serve as a

clog to digestion, and can mostly be recovered from the stools. Kassowitz, of Vienna, has asserted that phosphorus is beneficial, reasoning from the rapid and dense ossification which takes place in animals after the administration of phosphorus. I have frequented his clinic in Vienna and failed to observe that his patients did better than under other methods of treatment. Iron is often directly beneficial in the anæmia of rickets, but the most rapid improvement follows the use of fats, cream, and cod-liver oil. Cream is often better borne than cod-liver oil, and may be advantageously mixed with the prepared foods of hand-fed children. In most of the European hospitals cod-liver oil is given to rachitic children. It is remarkable to see how quickly a bronchitis or diarrhœa of weeks' duration will improve under the use of cod-liver oil. If the oil be vomited or cause diarrhœa, it may be given by inunction. Cheadle and most English authorities recommend raw meat, either scraped or chopped. This is very well taken by children. It is well in older children to cut off all starchy foods, giving chiefly meat, eggs, milk, and cod-liver oil. To effect a cure this regimen must be adhered to for months, although a substantial improvement will usually be seen in a few weeks. I have detailed at great length the etiology, the symptoms of rickets, and have described the manner in which rickets complicates various diseases of childhood. Although I am able to report only twenty-five cases, nevertheless the proportion of children affected, forty per cent., is large enough to demonstrate that rickets is a very common disease in this city, and I am persuaded that with wider observation and a keener insight into infantile disorders much that I have asserted as to its dangerous and often fatal influence will be conceded by American physicians.

WHY IS FREE HYDROCHLORIC ACID DIMINISHED IN GASTRIC CARCINOMA?

By A. V. PHELPS, M.D.,

CINCINNATI, O.

In 1879 Von der Velden, while examining about a score of cases of dilatation of the stomach, found that in those cases due to carcinoma of the pylorus the fluids removed by the stomach-pump were free from hydrochloric acid, while in those due to simple ulcer, and causes other than carcinoma, that if the acid was absent or diminished it was only temporarily.

These observations have since been confirmed, but as yet the absence of hydrochloric acid from the fluids obtained from a suspected stomach (unless the condition continued for some time) would not justify one in making a diagnosis of carcinoma, although its continued presence would be an excellent negative sign.

So generally has this been accepted that several delicate tests for free hydrochloric acid have been perfected, and limitations of the value of each drawn. In this day of medicine, however, we have ceased receiving such things and applying them in the empirical manner of our medical forefathers. We are very much in the state that young Barnacle of the Circumlocution Office reported Arthur Clennam to be in, that is, of "wanting to know, you know." The thing we want to know is, why is free hydrochloric acid diminished or absent in gastric carcinoma? It may be said that the free acid is diminished because of the lowered vitality of the body as a whole, the glands of the stomach imperfectly functionating because of the poor quality of the blood they receive, for Beaumont found in the gastric juice of that ever-reliable Alexis St. Martin a diminution of free acid during attacks of fever, or when the patient was anæmic. Hoppe-Seyler found no free acid in a number of cases of typhus he examined.

Is carcinoma due to a specific organism? By comparing its manner of growth and its clinical history with tuberculosis, a disease known to be of such nature, it seems most probable. We may have a local tuberculosis spreading by continuity and contiguity, as carcinoma usually does, or we may suddenly have a general carcinosis from ulceration of a local growth into a blood-vessel just as we have a general tuberculosis when the same occurs. That it is a specific disease best explains recurrence after imperfect removal, also the infection of the nearest lymphatic glands, which heretofore has been explained by the multiplication of arrested cells, and also by their so-called "spermatic action" on the cells of the gland in which they are stopped.

Many experts are hunting for this specific organism, and no doubt one will soon be found which can fill the position undisputed.

But what has all this to do with the absence of hydrochloric acid?

Riegel found that even normal gastric juice (taken from a perfectly healthy subject), when mixed with juice from carcinoma, has its digestive powers weakened, not converting albumin, as did other portions not so mixed.

Strümpell in speaking of this says: "This makes it seem probable that the normally constituted hydrochloric acid is in some way altered by the carcinoma."

Assuming carcinoma to be a specific disease, we think that the free hydrochloric acid is diminished or absent because it combines with ptomaïnes produced by activity of the organisms.

Analogy is often good argument for the thing unproven.

In the last few years quite a controversy has been going on between the laboratory-workers and the clinicians as to the way in which iodoform acts to be so useful in suppurating wounds.

It has now been proven that iodoform does not destroy the pyogenic germs, but combines with and renders inert their ptomaïnes, and thus the tissues being, relieved from the deleterious effects of the ptomaïnes, combat successfully the germs.

Clinical Department.

UNUSUAL CASES IN OBSTETRIC PRACTICE.

By JOHN TRUMBULL, M.D.,

VALPARAISO, CHILI.

I. *Painless labor.*—On October 6, 1887, I was called at 4 A.M. to see Mrs. W—— in confinement with her fifth child. The membranes were intact and cervix dilated to the size of a quarter, head presenting. Every five or six minutes uterine contractions came on. To call them "pains" would be incorrect, for the patient declared she felt nothing whatever, and there was not the slightest change of expression to indicate pain. A little moisture with staining was all that had warned her of approaching delivery.

In consequence of the absence of suffering, the quietness of the patient enabled me to carefully observe the uterine contractions with the finger against the bulging membranes, and it was interesting to note the remittent character manifest in each uterine contraction. There were always three or four distinct waves of contraction, each slackening a little before a stronger spasm followed, thus giving one the impression of what one might graphically describe by the curve of a muscle thrown into contraction by several succeeding induction-shocks. It is probable that, as the pains are intermittent as regards one another, they manifest a remittent type in the several contractions which go to form one "pain." Repeatedly since, I have sought to observe this in other cases, but the restlessness has made it impossible to confirm with the intact membranes what, however, is the impression given by the advancing head later on, of recession and advance alternating in one pain. The normal method of uterine

action is manifestly by successive spasms or contractions, each, after a slight letting up, being followed by a stronger impulse, and so gradually and by zig-zag reaching the acme of a pain, when temporary exhaustion follows and uterine action ceases, to be renewed in another set of increasingly stronger contractile waves after a given period of rest.

By 8 A.M. dilatation was complete, when I ruptured the membranes to hasten expulsion. As heretofore, this stage was likewise devoid of any discomfort even to the mother; and as the head passed the vulva, half an hour later, a feeble "Ah!" of surprise was all that escaped her lips.

The mother is an epileptic and slow intellectually, but when married, eight years ago, was bright and entertaining. All her confinements have been painless. As her previous medical attendant expressed it, "She never has any labor, but simply exudes her child." Her first labor was called "precipitate," which is very questionable in view of this case as followed. At that time she was ignorant of all that pertained to maternity, and thinking her bowels wanted to be moved, took oil, was surprised at its rapid action, went to the closet, and there dropped the child. It must have been that dilatation was perfectly painless, descent, while also without suffering, giving rise to the sense of fulness in the rectum and desire to stool. Dilatation of the cervix I cannot imagine to be ever accomplished by a single pain. Is it not rather probable that precipitate labors are, as this first confinement must have been, painless in the stage of dilatation; and that then a single contraction suffices to complete the stage of expulsion?

II. *Early rupture of fœtal membranes, with persistent loss of amniotic fluid and continuance of pregnancy.*—Mrs. T——, aged twenty-nine, the mother of two children, had her last courses the closing days of 1887. In January she was not unwell, breasts hardened and began to itch about the nipples, and leucorrhœal discharge was present. Never having had any nausea in her previous pregnancies, she concluded she was again with child. February 15th, when seven weeks along, while at work rearranging her pantry, she felt a sudden gush of something warm, which proved to be blood. For me it only remained to urge the continuance of the precaution taken, of keeping bed, and to order acid drinks and cold food. For a few days a slight chocolate-colored discharge continued, but ceasing, she was allowed at the end of a week to sit up in bed. This again precipitated a slight flowing, which with rest in the horizontal position disappeared. The light brownish discharge persisted, so she remained recumbent for a full month, when permission to rise was granted. The rusty discharge continued, and three days later there occurred a third loss of blood; but being then only three months gone and sick at the prospect of keeping bed for six months, she took matters in her own hands and determined to keep about and risk loss of her conception. Bleeding therewith ceased, yet occasionally there would be a sudden gush of an almost colorless liquid. This usually occurred toward morning, and she said she could always tell if it were going to come, because the evening before she was conscious of a "trickling inside." The vessel, when used after these sudden gushes, deposited little reddish masses the size of a pin-head. Digital examination showed an enlarged and slightly elastic womb, with cervix softened and admitting the first phalanx of the finger, though the internal os was closed. I expressed the opinion that with loss of fœtal life consequent on the hemorrhages a mole had formed, and advised that, so long as her health continued good, she await the natural efforts of nature to throw it off; urging this because the breasts belied death of the fœtus, and I could only explain the case by the supposition of a double conception, with death and subsequent degeneration of what was one fœtus, and continued though checkered growth of the second.

On May 21st the patient insisted that, while the same state of things had continued, she felt movements. Examination showed that the womb did not correspond with a nearly five months' conception. It was broad below and so small that between the uterus and the umbilicus four fingers could be laid; yet, to my surprise, auscultation disclosed a fœtal heart.

June 12th.—Developments have led to a change of diagnosis; for, unusual as it may seem, we have to do with the ruptured amniotic sac of a living child. After two or three days free from any discharge, which has meanwhile become colorless and of an odor like that of the amniotic fluid at labor, the womb will be up, or even above, the depression of the umbilical cicatrix; and then, again, after leakage and flow, it is found contracted, reaching only half-way between the umbilicus and pubis, when fœtal movements become very perceptible to the patient, and also to the touch. The trickling and, later, sudden gushes of fluid in the early morning, after several hours of recumbency, have now given place to a more disagreeable loss of amniotic fluid at any time when in a sitting posture. The amount lost is remarkable. Lusk calculates the whole quantity collected during pregnancy at from one to three pints; but here the patient, in a short half-hour, will thoroughly soak five or six double napkins, the womb grow small; yet within twenty-four hours be high again and ready for another similar drain. This has been of daily occurrence during the past fortnight. By careful estimation of the amount of water necessary to soak the napkins as I have seen them, I find the daily loss cannot be less than from sixteen to eighteen ounces.

Only once has there been any disposition on the part of the womb to repel and expel its contents, and then not from the loss of amniotic fluid, but from a fright occasioned by an outbreak of fire in the next house. When, for the first time, the waters came away in an upright position, regular pains came on, and every preparation was made, only to be followed in a couple of hours by cessation of uterine activity.

June 20th.—No change, and nothing further to record than the continued loss of amniotic fluid in even possibly larger quantities, entailing marked variations in the size of the womb. Head down with back to the right is clearly definable on palpation.

July 4th.—Patient, yesterday, had a fall eight feet in height. She was much shaken up and thought labor would surely come on, yet it ended as on the previous occasion when a mental impression threatened to be the precipitating cause of miscarriage. Daily loss of fluid continues. Patient annoyed by the moisture and persistent use of napkins, but her general health is very good.

July 31st.—No diminution in flow. Amount some days, as I have often estimated approximately, reaches as much as eighteen and twenty-one ounces. For three days past the central portions of the saturated napkins have been stained with blood. To-night she complained of dragging sensations, and bearing-down pains. The womb was found close upon the fœtus and reaching only to an inch below the navel. Head no longer above the brim, but with examining finger encountered an inch from the vulva. Cervix well back, and internal os patulous, admitting two fingers, which could make out the sutures.

August 1st.—After all, she rested well last night, and in the morning said the womb was high again, though since rising the flow and bearing down had recurred.

August 2d.—Last evening had the same descent of the womb and its contents, but to-day the staining with blood has ceased.

August 8th.—The fact of persistent daily loss of large quantities of amniotic fluid, without provoking miscarriage, alone merits recording. Patient says she never felt better.

August 15th.—On the eleventh the city was visited by a sad calamity. The dam of a reservoir, on one of the hills, eight hundred feet above the city, broke and precipitated its waters down a ravine, carrying everything before it—trees, enormous bowlders, houses, and, of course, everyone in its way. There was frightful loss of life and great damage to property, as the torrent poured through one of the main streets of the town on its way to the sea. Mud

and débris reached to the patient's door. She saw some half-drowned persons crawling out of the wreckage, wounded and dead being removed, and had some of the unfortunates under her roof and care. By nightfall the bloody staining reappeared. Bearing-down pains in the back, and cramps in the legs were present, but all to no purpose. At irregular intervals these recurred till last evening, when the pains persisted. I saw the patient at 1 A.M.; os dilated to the size of a silver dollar. Dilatation was slow, and it was 7 A.M. before the os was fully open, when a few pains sufficed to expel the child.

The placenta came away in a quarter of an hour, showing along its rim a white, cicatricial-looking line where loosening had evidently occurred. There was nothing whatever to indicate a double conception, while the whole course of the pregnancy, absence of bulging membranes or loss of waters in the labor, clearly proved the diagnosis.

Rupture of the membranes is spoken of as a certain, though not always speedy, method of inducing labor. I once had a case where at the eighth month the waters drained away, but after a few days' rest the lady, a primipara, went by rail to her mother's house, a distance of one hundred and fourteen miles, and did not have her child till the completion of the ninth month; but I have never heard of a case where the membranes ruptured as early as the seventh week, and yet pregnancy continue uninterrupted so long. The tolerance of the uterus was remarkable, having defied a strong fright and fall, in addition to the constant escape of its fluid contents; and but for the circumstances attending the final onset of labor, I think that pregnancy might have continued to its natural limit.

The child, a male, weighed three pounds fourteen ounces, had nails developed, and for three weeks was unable to suckle. Still he had a robust look, did well, and has thrived. The only result of the abnormal conditions in which its uterine life was passed was a slight talipes varus of the right foot, which massage has corrected.

III. *A large haul.*—At 8 A.M., April 6, 1889, I was called to see Mrs. D——, a stout, large German, in labor with her sixth child, whose birth was due on March 27th. Children had all been large, between nine and twelve pounds. One, though a head presentation, had been lost through strangulation of the cord about the neck, as the midwife said.

The lady, a regular patient, had been advised to have me present, but delicacy about being attended by a man forbade. When I arrived the midwife said it had been an O. L. A., that head had been born three-quarters of an hour, and that she had been unable to effect rotation and extraction; that she had felt an arm displaced backward, and fancied it was the cause of obstruction. The head was in the antero-posterior position, with occiput beneath the arch. Child's face livid, without reflex on introduction of finger in the mouth, and no heart-beat to be heard. Having informed the husband that the child was dead, chloroform was administered. On then introducing the hand along the mother's left side, the posterior shoulder, the left one, could be felt in the cavity with its arm by the side of the body; while the right shoulder was jambed up against and above the pubic bone, slightly to the right of the symphisis, and was evidently the obstructing cause of delayed delivery. Some difficulty was experienced in trying to push the shoulder upward to relieve of pressure, and then forcible rotation of the head and shoulders to the right was effected, so as to bring the shoulders into the transverse position; but, even then, considerable effort was requisite to draw down and extract. The following measurements taken at the time may be of interest: Weight, 18 pounds 4 ounces; length, 61 ctm.; occipital-frontal circumference, 39 ctm.; breadth of shoulders, 23 ctm.; circumference of shoulders, 54 ctm.; circumference of pelvis, 42 ctm. I do not remember to have ever seen reference to obstruction arising from the position of the shoulders after birth of the head, nor to the necessity of forced rotation in a direction the opposite of that which would be the normal mechanism of delivery, but which is alone the practical plan when the shoulder gets fixed above the pubic bone.

A YOUNG LIVING FŒTUS.

DR. J. L. NASCHER, of New York, writes: "I was called to Mrs. N—— on May 7th. She was delivered of her first child, January 22, 1888. After May, 1888, her menses returned regularly, the last time on November 9, 1888. A number of circumstances put it beyond doubt that conception took place after November 15th. From November 15th to May 7th, nothing unusual occurred in her pregnancy. On the latter date she complained of a sudden gush of water and some blood from the genitals, followed by slight pains. It was impossible to prevent miscarriage, which occurred on the 10th, at 2 A.M. The child gave a few gasps and was laid aside while the mother was attended to. In a few minutes the child began to cry. It was at once wrapped up in cotton. A little fennel-tea, the nurse says three teaspoonfuls, was given, which the child eagerly took. This was at 4 A.M. At ten o'clock the child again received three spoonfuls. At noon pinkish blood oozed from the nose. The feet and body became cold, and the child died at 12.15, living over ten hours. It measured eleven inches, and weighed less than two pounds. The eyes were closed and could not be opened. The fontanelles were very large and high, beating so fast as to appear like a tremor. The heart beat so fast that I could not count it, while the pulse was not distinguishable. Even the nails were not seen. There is no doubt that this child was of less than six months pregnancy, and as such the case may be of interest."

Progress of Medical Science.

THE ACTION OF PARALDEHYDE.—Dr. John Gordon has published an experimental investigation of the action of paraldehyde, of which the following is a summary: 1. Paraldehyde caused an increase in the excretion of urea. 2. It did not in any marked way affect the quantities of chlorides excreted. 3. It did not invariably increase the excretion of the fluid constituents of urine, but in the majority of cases diminished them. 4. The odor of paraldehyde, when given in large doses, was found in the urine, showing that some of it probably passed unchanged through the system. 5. After the full dose of the drug the respirations were slowed, and rendered tranquil and steady. 6. It had no appreciable effect on temperature. 7. In cases of average health without sleeplessness it did not have any hypnotic influence except in large doses. 8. It caused no loss of appetite. 9. There was sometimes a tendency to perspiration under its influence, which atropine controlled. 10. The blood-pressure was only slightly reduced by the smaller doses, the large dose reducing it more, but only after distinct slowing of the respiration. 11. The pulse was slowed. 12. It diminished the reflex excitability of the spinal cord. 13. It had a peripheral influence in controlling sensation. 14. It speedily diminished, and in large doses destroyed, the irritability of motor nerves. 15. Equal doses diminished the excitability of motor nerves sooner than that of muscle. 16. Small doses first slightly excited and then diminished the excitability of muscle-substance. 17. Large doses speedily destroyed (temporarily) the irritability of muscle-substance. 18. There was a tendency to complete recovery in the muscle after a small dose, but seldom complete recovery after a large dose. 19. Curarized muscle showed increased excitability over non-curarized muscle when treated with an equal dose of paraldehyde and equally stimulated. The advantages of the drug as a hypnotic, to which group it distinctly belongs, depend on the following points: 1. It is not a cardiac depressant. 2. It has no marked period of toler-

ation, since in some cases of insomnia from overwork the drug has been taken in the same dose for some months with equally good hypnotic results. 3. No marked craving for the drug seems to be induced by its use. 4. It does not exercise, except in large doses, a hypnotic effect on a person not suffering from sleeplessness; hence there is no probability of its abuse. 5. It has not a marked period of excitement before the hypnotic action takes place. 6. Its action is speedy, patients generally falling asleep within ten minutes after its administration. 7. The patients may be aroused while under its influence without any disagreeable or confused sensation. 8. The sleep which it produces is tranquil and quiet, with diminished respirations; this slowing of the respirations in many pulmonary diseases is of distinct advantage. 9. It is not liable to disorder the digestion. 10. In many cases it is gently laxative in its action. From the experiments which were performed on the lower animals its use as a narcotic in cases of insomnia with slight pain is not contraindicated, since the author's experiments with frogs show that it controls, to some extent, the sensory nerves; and the experiments with cats prove that, in large but non-poisonous doses, it exercises a narcotic influence. And it is possible that, since a large amount of the drug is excreted by the lungs, its vapor may exercise a narcotic influence on the terminations of the sensory nerves of the lung-tissue while it is being expired. Dr. Gordon's method of prescribing is in doses of from 40 to 60 minims for adults, well diluted with cinnamon water, adding a little sirup of tolu and compound tincture of cardamoms.—*The Therapeutic Gazette*, April 15, 1889.

THE OPERATIVE TREATMENT OF PROLAPSE OF THE RECTUM.—Dr. Mikulicz has described his method of dealing with this affection and has put on record seven cases in proof of its safety and efficiency (*The London Medical Recorder*). Of prolapse of the rectum there are, it is pointed out, three forms. The first and simplest of these, prolapsus ani, is a mere ectropium of the mucous membrane of the rectum in which the other coats of the gut, especially the musuclaris, are seldom involved. In the second form, that of true prolapsus recti, the protrusion consists of all the coats of the intestine, and, like the invaginated portion in intussusception, presents on section two tubes of intestine, one within the other, and in contact by their serous surfaces. The third form, to which the name is given of prolapsus coli invaginati, is really intussusception of some part of the colon, and may be readily distinguished from the other forms by the fact that the external layer is not fixed to the anus, and that the finger can be passed into the rectum by the side of the protruded mass. In cases of chronic prolapsus recti, with ulceration and gangrene of the exposed mucous membrane, and a persistent tendency to further protrusion, excision of the protruded portion of the intestine is, according to Mikulicz, the most suitable treatment. The limited excisions devised by Dieffenbach and Dupuytren are, it is stated, often useless and do not guard against prolapse, and cauterization, though a milder proceeding, is still not free from risk and may cause stenosis of the anal portion of the gut. Partial excision and cauterization will, it is true, result in contraction of the relaxed and softened sphincters, and of the immediately superjacent portion of rectum, and the constricted and rigid extremity of the gut will, if the case be a mild one, resist further protrusion from above; but in too many instances the *vis a tergo* overcomes this resistance and the cicatricial tissue yields sooner or later to renewed prolapse of the rectum. It is necessary, he states, to shorten the elongated and displaced rectum, and, in correspondence with this indication, to resect a large portion of the prolapse. This is held to be the most rational course in all old cases of prolapsus recti, and particularly after relapse. The operation described in this paper was first performed with success by Nicoladoni, and resembles in some respects one advocated by Esmarch, in which, before resection, the upper part of the prolapsed gut is fixed tightly by ligature to a bougie introduced into the rectum so as to prevent any exposure of the peritoneal cavity. Mikulicz, after having passed two sutures through the free lower end of the prolapse, in order to stretch and fix in required positions the gut, makes a transverse incision through the anterior layer of the prolapsed mass, about half an inch below the anal margin. The inner tube of the prolapse having been thus exposed, the serous margins of the outer and inner layers are brought together by sutures, in order to shut off the peritoneal cavity. The inner tube having been divided transversely along the whole length of the outer incision, and the intestinal canal opened, the cut edges of the inner and outer tubes are then fixed together by a second row of sutures. The posterior surfaces of the tubes are then divided and sutured in like manner, and the whole of the prolapse thus detached. In most cases the peritoneal sac does not descend between the layers of gut behind, the space being usually occupied by the mesocolon which contains numerous vessels. In this operation Mikulicz insists on the use of silk in preference to catgut for the material of the sutures.

CHRONIC ARSENICAL POISONING.—In a contribution bearing on the wholesale arsenical poisoning which occurred last year at Hyères (France), in consequence of the accidental substitution of white arsenic for gypsum in wine, Dr. Duhrandy summarizes the general effect observed among the victims of the error (*The London Medical Recorder*). Upward of four hundred suffered to a greater or lesser extent, and several cases proved fatal. *A. Digestive apparatus.*—Gastric derangement was the first symptom in every case; many patients suffered from nausea, vomiting, and diarrhœa, but in most instances these soon passed off, a sort of tolerance being established. Their duration varied from one to four days. In other cases dryness of the mouth and fauces, or ptyalism, with retro-sternal and epigastric constriction, were complained of, though seldom to such an extent as to necessitate recourse to a medical man. *B. Respiration.*—Acute bronchial catarrh was an early symptom with many of the patients, following the digestive disorders. It was more persistent and constituted a sort of second stage of the toxic phenomena. The symptoms, as a whole, bore much resemblance to ordinary influenza, but the secretion was less abundant and there was marked motor and sensory disorder (lassitude, prostration, tingling, etc.). *C. Muscular system.*—The muscular weakness varied in intensity from simple weakness of the muscles of locomotion to complete paresis. This, however, was not due to paralysis but to lack of nervous energy. Some patients, nevertheless, exhibited paralytic symptoms of an ephemeral nature. The patellar reflexes were diminished or abolished, and this still persists in certain of the victims. *D. Sensory.*—The disorders of sensibility were universal though of variable intensity. They were exceedingly obnoxious to treatment, and consisted in tingling in the extremities, with loss of tactile sensation and pain. The pain complained of was headache, pleurodynia, shooting pains in the limbs, etc. The latter were, in some instances, so severe as to prevent sleep. Many complained of a sensation of heat internally, especially distressing at night. Tactile sensation was sometimes dulled, sometimes hyperacute, at others a blend of the two. The special senses were less frequently affected, but in some cases deafness, with or without noises in the ears, was complained of. In two instances fetid sweats were noticed.

THE PLACE OF SACCHARIN IN PHARMACY.—Under this title Dr. Attfield has published a pamphlet in which he shows how saccharin may be most advantageously employed in the compounding of numerous pharmaceutical preparations, reducing very considerably the bulk of some and rendering others much more palatable.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, June 15, 1889.

THE HEALTH OF JOHNSTOWN.

THE Johnstown calamity has had its horrors presented from many points of view. Flood, fire, devastation, and death have accentuated its different aspects until the high lights of the dreadful picture seem to have borrowed their tints from a yawning inferno. No description can probably do justice to the experience of the awful hours when rushing torrent and hissing fire fought for the mastery with death. Now that all this part of the dreadful drama is over, when the waters have again found their level, when the town is a mud-flat and its dead buried in the jam of trees, timber, roofs, and rubbish, the serious thought of the dazed survivors centres upon the difficulties of repairing damages and making a fresh start. Thanks to the generosity of the public there will be no want of funds to make this pecuniarily possible. In the meantime there is much to be thought of bearing upon the present and future welfare of those who are left. Time is required to clear away the immense accumulation of débris. Already fears are expressed as to the safety of this stricken people from disease and further desolation consequent upon the accumulation of putrefying bodies in the ruins. Happily there is but little cause as yet for grave anxiety.

The difficulties, great as they are, in the way of extricating the bodies are not insurmountable, and it is to be hoped that in a few days more the pressing problem will be satisfactorily solved. Many theories have of course been advanced as to the dangers of water-pollution, of typhoid, and other fevers, but such theories are not founded upon sufficiently scientific data to give them due weight. The situation is bad enough, but it must be conceded, if we know anything of the etiology of typhoid, that there should be no fear from the ordinary decomposition of human bodies. Unless the typhoid germ is present in one or more of the submerged bodies, it is perfectly safe to assume that typhoid fever will not appear, no matter how much the water may be otherwise polluted. The same may be said of other essential fevers. It is quite possible also that the pollution of the stream will not be so great as is supposed. Submerged bodies do not decompose as rapidly as those exposed to the air, and the products of decomposition are different and less dangerous. The fact that running waters purify themselves by oxidizing and depositing decomposed products is a well-recognized one, and serves to explain the immunity of villages that are supplied by distant but polluted sources. While such a condition of things is not desirable on æsthetic grounds, there is still some comfort in its contemplation in connection with a more than ordinary stream-pollution, and a desire to hope for the best, even in the present emergency.

In reference to the bodies themselves, there is nothing to be done but to remove and bury them as quickly as possible, as disinfecting them or destroying them by fire is now out of the question. The more rapidly this work goes on the better. What is perhaps more dangerous to the surviving population than water-pollution, or anything that can come directly from emanations, are the depressing effects of the exposure, privations, and sorrow which have been so much a part of the experiences of that great calamity. The shock of the ordeal has doubtless left its mark upon the majority of those who have passed through the dreadful trial. It has already shown itself in the general air of melancholy which prevails, and in the lowering of the vital energies which is becoming more and more apparent. A people in such a condition would invite malignity or a high death-rate for any sickness, should the latter once get a start. Fortunately, this region is reported to be still free from any indications in that direction, and it is gratifying to know that, whatever emergency may arise, there are generous hearts and willing hands reaching toward the ill-fated valley from every portion of the country. The present sanitary arrangements are beyond criticism and are accomplishing all that can be expected, medical aid is plentifully supplied, and the hospital arrangements are in every way excellent. Therefore let us be patient and hope for the best.

THE DIFFERENT MODES OF TUBERCULOUS INFECTION.

SINCE the establishment of the specific character of tuberculosis, much attention has been paid to the various and peculiar ways in which it may invade the system. While the lungs and alimentary tract are the chief and primary areas of attack, it has been shown to develop in many other curious ways. It has been shown that post-mortem sores are, as a rule, forms of local tuberculosis. The case is reported of a woman who contracted tubercle of the skin of the hand from washing the clothes of her tuberculous husband. Another case is reported of tuberculosis of the genital organs resulting from a circumcision, in which the wound was sucked by a tuberculous operator. Dr. Finger has reported a case of apparently general infection as the result of a tuberculous dissection warts. From two different sources—Drs. Spillman and Haushalter, of Paris, and Hoffmann, of Dresden, it has been made probable that flies can swallow and carry with them the active contagion of tuberculosis.

The question whether tuberculosis can be directly inherited, *i.e.*, that an infant can be born with bacilli in the tissues derived from the mother or father, is still unsettled. If the fœtus is infected, it is safe to say that it is not through the ovum or spermatozoa, but through the placental circulation. Johne claims to have proved placental infection to exist in the cow; and Baumgarten, as well as some others, affirm that a child may be born with bacilli tuberculosis in its tissues, which may remain latent for years, or even during the lifetime. Landouzy and Martin have

caused tuberculosis by inoculating animals with the placenta of tuberculous patients.

There is considerable evidence, therefore, to show that tubercle may be directly inherited from the mother, but never from the father. And the great probability is, that instances of direct inheritance of tubercle are very rare indeed.

Dr. Mosler, of Greifswald, has tried to induce intestinal tuberculosis by feeding animals with tuberculous matter. He failed, but claims that a patient who was suffering from pulmonary tuberculosis infected her intestinal tract by swallowing the sputum. The results of investigations regarding the susceptibility of the alimentary tract to contagion are, on the whole, not such as to justify alarm. According to Nocard, the meat of tuberculous animals is a pretty safe food. Since even tuberculous cows do not always have tuberculous mastitis, the danger from milk infection is not great.

Now that attention is being so actively directed to preventing phthisis, as well as relieving and curing it, suggestions of the most various and unique character may be expected. Dr. Z. Petresen, of Buda-Pesth, has devised an inhaler, something like the nargileh, or water pipe. Instead of water, the following solution is used:

℞. Eucalyptol,
Creasote,
Olei terebinth ..... āā 2.0
Iodoform 0.1
Aquæ destil 100.0
M. Sig.—For two days' inhalation.

Persons predisposed or exposed to phthisis are advised to inhale air drawn through this mixture, daily. It is believed that it tends to saturate the system with the antibacillary agents. The same fluid may also be used more conveniently in the small nasal inhalers, such as were described and introduced here by Dr. Beverley Robinson.

BURIED ALIVE.

THE belief that people are ever nowadays buried alive, or ever have been, except for criminal or judicial purposes, is one that is widespread, but also one that has very little foundation in actual fact. We venture to say that there are not in history any authentic records of cases of burial alive, where the deceased has been carefully examined by physicians, or even by intelligent friends. Of recent evidence of burial alive, there is certainly nothing of value. The *Medical Press and Circular* of May 13, 1874, reported the premature burial of a woman, six hours after supposed death. But no evidence that the woman was not dead is given. The *British Medical Journal* of January 21, 1871, cites the case of an infant that was *nearly* buried alive, but was heard to cry in its coffin. Here, too, the evidence as to the validity of the facts is wanting, while in effect the child was not buried alive. Another recent case occurred at Naples, in 1871 A woman in a state of trance is said to have been buried alive. The Court sentenced both the doctor who signed the certificate, and the Mayor who permitted the interment, to three months' imprisonment for "involuntary manslaughter."

If these and other cases are analyzed, it will be found either that there was no proof of the premature burial, or else there was gross carelessness and criminal haste on the part of attendants.

The belief in burial alive should disappear with the belief in ghosts and other "bugaboos." It is, of course, possible that persons may be buried alive through some criminal conspiracy, or through some manifestation of monumental incapacity on the part of friends; but such contingencies can be easily avoided in modern life.

LAURA BRIDGMAN.

THE recent death of Laura Bridgman has called out a great many reminiscences of this remarkable woman. We do not at this day realize the intense interest which her case at one time aroused; and certainly there has been no reference, so far as we know, to the important data her history furnishes to pedagogy and psychology. The general facts regarding Laura Bridgman are well known. How, at the age of twenty-six months, she lost entirely her sense of sight and hearing, and to a great extent her sense of smell and taste; and how, until she was eight years of age, she received no attempts at education. At this time, it is known that she had quite lost all memory of her life before her sickness; she retained, absolutely, no visual or auditory memories. Dr. Howe's success in teaching her to talk with the hands, to write, read, etc., is also a familiar story.

Most interesting now to medical men is a study of her physiological and psychological condition, made by Professor Stanley Hall, just ten years ago. He found her totally unable to see or appreciate sensations of light from any kind of stimulus. Her deafness was equally complete; but she could appreciate different kinds of vibrations, and even knew her friends by their step. This must have been done, however, by the tactile or muscular sense. Her sense of smell and that of taste were dull.

The tactile sense showed the most acute and remarkable development, and, as recorded by Hall, was as follows:

Tip of tongue	$\frac{1}{30}$ inch.
Tip of right forefinger, volar surface	$\frac{1}{38}$ "
Hips	$\frac{1}{40}$ "
Tip of second finger	$\frac{1}{51}$ "
Tip of third finger	$\frac{1}{56}$ "
Tip of fourth finger	$\frac{1}{73}$ "

The sensitiveness of the face at various parts was also very great, and the measurements in general showed an acuteness of touch two or three times greater than the average.

But the ordinary tests made with the artheriometer gave no adequate idea of her exquisite contact-sense, which amounted to a kind of normal hyperæsthesia, so that even specks of dust alighting on the face and hands were appreciated and annoyed her. Curiously enough, her temperature-sense was below the average, and the same was true for pressure sensations and electrical irritations. Her tactile memory was so extraordinarily developed that she could at once recognize friends whom she had not seen for a long time by a touch of the hand. Her muscle-sense, so far as it could be tested, was not unusually acute. The sense of equilibrium and of direction was very well developed. Curiously enough, she was easily made dizzy and even nauseated by movements of rotation; and it was thought that possibly the semicircular canals were not destroyed by the disease which destroyed her hearing. Yet this seems somewhat improbable.

A very careful inquiry showed that the sexual instinct failed to mature, or show itself in any specific way. She never acquired any notion of the ways and means of its gratification. Although the strongest of human instincts thus failed to develop itself, yet with very little teaching there did develop fresh and original intuitions as to the nature of God and a first cause, and as to her personal responsibility and sense of right. It is encouraging to human progress to know that moral and religious instincts may spontaneously develop and dominate rather than the sexual.

News of the Week.

SCIENCE AND POLITICS AND THE PARIS EXPOSITION.—There is, it appears, in Berlin a society composed of surgeons of the army reserve, and presided over by one Herr Wasserfuhr. This society has voted that its members abstain from taking part in the numerous scientific congresses to be held in Paris this summer, in connection with the Exposition. This decision is thought simply to indicate a desire on the part of Bismarck to have Berlin physicians "boycott" the Paris show. Naturally, our French contemporaries are somewhat indignant, and in justice it should be said that many Berlin physicians regret the action taken by their colleagues as most unwise.

M. DUPRAT, well known as a physician, littérateur, and musician and composer, died recently at Paris, aged sixty-five.

A MEDICAL PRESS ASSOCIATION has been organized in France. It is composed of the editors and proprietors of the numerous medical periodicals of that country. It meets three times a year, when business is transacted and a "confraternal" dinner is eaten.

THE "MEDICAL PRESS OF WESTERN NEW YORK" is to be consolidated with the Buffalo *Medical and Surgical Journal*.

CLARK UNIVERSITY.—The first announcement of the opening of this university has been issued. Teaching will be given in mathematics, physics, chemistry, biology, and psychology. The teachers in biology and psychology are Professor Hall, Dr. H. H. Donaldson, Dr. E. C. Sanford, Dr. Warren P. Lombard, and Dr. F. Mall.

THE GREATNESS OF CHICAGO is constantly asserting itself in some unique way. One of its medical colleges has recently graduated, to put it euphemistically, a colored medical lady.

THE STUDY OF THE PROPHYLAXIS OF PHTHISIS is developing some novelties. Among these is a pocket spit-cup, made of glass, and holding about three ounces. It was devised by Dr. Dettweiler, of Frankenstein. It obviates the necessity of using the handkerchief, or the carpet.

A MEDICAL REGISTRATION LAW IN OREGON.—Governor Pennoyer, of Oregon, has decided to allow the Pope bill regulating the practice of medicine to become a law without his signature. This law provides for "three persons from among the competent physicians of the State," to "issue certificates to all who shall furnish satisfactory proof of having received diplomas or licenses from legally chartered medical institutions in good standing, of whatever school or system of medicine."

THE BISHOP AUTOPSY.—Drs. J. A. Irwin, Frank Ferguson, and H. Hance were arraigned in Court on Tuesday, on indictments for misdemeanor, found against them by the Grand Jury for "unlawfully making a dissection of the body of Washington Irving Bishop, on May 13th, without authority of law, and not in pursuance of permission given by the deceased." They pleaded not guilty, and were each held in $500 bail.

BROOKLYN PHYSICIANS INDICTED.—The attacks of a certain Brooklyn paper upon Dr. Mary Dixon Jones and her son, Dr. C. N. D. Jones, have culminated in an indictment by the Grand Jury, and in throwing a serious cloud over the reputation of these heretofore highly esteemed physicians. While we have not all the evidence of the case before us, we know that most of the charges are utterly false. From the known standing and skill of the accused, it is very safe to infer that they are the victims of misrepresentations and unfair charges. We feel sure that a trial will exonerate the Drs. Jones, and meanwhile we trust that the profession of this city and Brooklyn will extend to them support and sympathy.

THE AMERICAN CLIMATOLOGICAL ASSOCIATION holds its Sixth Annual Meeting in Boston, June 24 and 25, 1889, under the presidency of Dr. V. Y. Bowditch. The following programme is announced: Address by the President, Dr. V. Y. Bowditch, Boston, "Comparative Results in Ninety Cases of Pleurisy, with Special Reference to the Development of Phthisis Pulmonalis;" "A Study of the Summer Climate of the Massachusetts Coast," by Dr. William D. Hodges, Boston; "Reports of Cases of Acute Miliary Tuberculosis," by Dr. John C. Munro, Boston; "The Mortality of Acute Lobar Pneumonia: A Study of all the Cases treated at the Massachusetts General Hospital, from the First Case in 1822 to the Present," by Drs. C. W. Townshend and A. Coolidge, Jr., Boston; "Consumption as I have known it," by Dr. E. P. Hurd, Newburyport; "The Influence of Climate and Season upon Normal and Abnormal Manifestations of Nervous Activity," by Dr. Walter Platt, Baltimore; "Open-air Travel as a Cure and Preventive of Consumption, as illustrated in the History of a New England Family," by Dr. Henry I. Bowditch, Boston; "Rest and Exercise in Diseases of the Heart," by Dr. A. L. Loomis, New York; "The Basis of Rational Climato-therapy," by Dr. Griffith E. Abbott, Bryn Mawr, Pa.; "Ocean Therapy," by Dr. Albert L. Gihon, Surgeon, U. S. N.; "The Vital Statistics of Two Thousand Persons in an Ocean Atmosphere," by Dr. A. N. Bell, New York; "The Psychological Factor in selecting a Climate for Invalids," by Dr. E. O. Otis, Boston; "The Wakefulness of Neurasthenia as affected by a Residence at the Sea-side," by Dr. W. H. Daly, Pittsburg, Pa.; "The Relations of Sandy Soil and Pine Forests to Pulmonary Phthisis, with Special Reference to the Pine Belt of New Jersey," by Dr. Isaac H. Platt, Lakewood, N. J. *Discussion*—Hæmoptysis from Chronic Pulmonary Disease: "Pathology," by Dr. G. M. Garland, Boston; "Clinical Significance," by Dr. J. T. Whittaker, Cincinnati; "Climatology from Stand-points of Etiology and Therapeusis," by Dr. R. G. Curtin, Philadelphia; "Other Treatment," by Dr. J. B. Walker, Philadelphia; "Remarks on the Treatment of Pulmonary Phthisis," by Dr. J. C. Wilson, Philadelphia.

THE PENNSYLVANIA STATE MEDICAL SOCIETY, which was to have met last week at Pittsburg, was obliged, on account of the floods, to adjourn its meeting until September.

REGARDING THE DEATH OF DR. CRONIN, *The Medical Standard* says, "The absolute control which politicians have over charitable institutions is such that everything that stands in the way of their spoils must be got rid of. The man who has the hardihood to stand up against existing abuses is marked for slaughter. This has been recently exemplified by deep conspiracies in this city, which have led to the murder of one physician and the deliberate attempt to ruin the character of two others, each of which comes under the head of political crime. That the murder of Dr. Cronin was for political purposes no one doubts."

THE NEW HAMPSHIRE STATE MEDICAL SOCIETY holds its ninety-eighth annual meeting at Concord, on June 17th and 18th.

THE POPE'S PHYSICIAN.—Dr. Giuseppe Lapponi, a young and distinguished graduate of the Bologna school, has just been appointed body physician to his Holiness Pope Leo XIII., in succession to Dr. Valentino, deceased.

Obituary.

JAMES B. HUNTER, M.D.,

NEW YORK.

ON Monday, June 10th, at his residence in this city, died, in the prime of life, one of our leading gynecologists, James Bradbridge Hunter.

Dr. Hunter was born of English parents, in Geneva, N. Y., April 30, 1837. At the time that the Civil War broke out, in 1861, he was studying medicine in Cincinnati, but he immediately abandoned his studies and volunteered, joining the Sixth Ohio Regiment, and soon rose to the rank of first lieutenant and adjutant. Afterward, having passed the examination of the Army Medical Board, and received his diploma, he exchanged to the Medical Staff, and was assigned to the Sixtieth Indiana Regiment as Assistant Surgeon, later becoming Surgeon, and with this he saw active service under Grant at Vicksburg and other points. Upon the close of his connection with the army he graduated at the College of Physicians and Surgeons, in this city, in 1866, and afterward continued his studies at the Moorfields Hospital in London. At this time he was studying with a view to becoming an oculist, an intention which he afterward abandoned and identified himself with the field of gynecology. He was appointed House Surgeon to the Woman's Hospital in this city in 1867, and after serving his term in that capacity became Assistant Surgeon to the same institution in 1871. This position he held until his appointment by the Board of Governors, in 1878, as Attending Surgeon to the Hospital.

At the time of his death he was Attending Surgeon to the Woman's Hospital; Visiting Surgeon to the Cancer Hospital, of which he was one of the founders; and Professor of Gynecology in the New York Polyclinic.

He was for many years very successful as the editor of the *New York Medical Journal*, but the increasing demands of practice upon his time obliged him to abandon all literary work.

Dr. Hunter's career presents a very striking example of success attending upon late development; achieved by a reserve force, the existence of which was long unrecognized; accomplished even after the competitor had apparently given up all intention of striving for it. Up to the year 1871, when, at the age of thirty-four, he was appointed Assistant Surgeon to the Woman's Hospital, he gave almost all his time to literary work and evinced little desire to accumulate a practice. That event appeared to arouse his dormant ambition and to stimulate his energies. His whole soul was henceforth thrown into his work; no effort was too great; no sacrifice too exacting if by it he could advance his knowledge and experience in the department to which he had now completely devoted himself, and before many years had passed he had acquired a skill as a diagnostician and an ability as an operator which made his name very generally known to the profession and the public.

In the spring of 1882 he married Miss McPherson, of Frederick, Md., and during the seven years which have elapsed since that time it is safe to say that the practice, the reputation, and the increasing skill of no one in the profession of medicine has more rapidly and steadily advanced. Nor will any who are familiar with the facts dispute the assertion that at the time of his death he stood well forward in the ranks of gynecology as a practitioner, as a teacher, as a writer, and as an operator. Success came to him late, but it came to him in the day of his full maturity and assured mental force, and it found him well-poised, cautious, and prepared. Had life been spared to him, the end of the next decade would have seen him among the very leaders of his specialty.

By nature reserved, reticent, and undemonstrative, he was not one to have many intimates; but by those who were brought into close contact with him he was much beloved. He was true to his friendships; faithful and devoted; uncompromisingly loyal to all who possessed his affection. In times of trial the tenderness which he would display was a marvel to those who had not previously seen this characteristic tested, and there were no limits to the gentle, loving sympathy which the sufferings of others would call forth. At such times he was truly as gentle as a woman, strong and stern man as he seemed to be in the eyes of the world.

In no calling in existence are charity and kindness to the poor so constantly, so lavishly, and so unobtrusively bestowed, not excepting even in the far nobler profession of divinity, as in medicine! And yet, even in this lavish field, his quiet, unostentatious, almost morbidly secret, bestowal of aid to the needy and suffering were quite remarkable. In his efforts but one thought seemed especially to occupy his mind—the desire to leave no trace by which his acts could be known to the world.

He was faithful to every duty in life allotted to him. As a writer he was cautious in expression, candid in statement, and attractive, though not brilliant in style. As a teacher he was dististinguised by the same characteristics. He always held his classes even when following more experienced teachers in his efforts; and he did so, not by eloquence or by oratorical display, but by honest teaching and laborious demonstration.

No one can tell why any man succeeds as a practitioner. The cause of success in this cannot be weighed in the balance of criticism. Whatever the secret of it may be, Dr. Hunter showed during the last decade of his life that he possessed it in a decided degree.

As an operator he was cautious, without timidity; bold, without recklessness; conservative, without prejudice against progress. His motto seemed to be:

> "Be not the last by whom the new is tried,
> Be not the first by whom the old is thrown aside."

The loss of such a man cannot but be felt by the profession which he adorned, the community for which he labored, the many friends who knew his worth and loved him for his virtues. In a great city like this the profession of medicine is full; but not of such men as this! The demand of the public for physicians is more than supplied; but not with such material! Even in this whirl of metropolitan life, activity, and energy, his loss will be felt; even here it will be long ere the memory of this good man will fade away.

Society Reports.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Eleventh Annual Congress, held in Washington, D. C., May 30, 31, and June 1, 1889.

FIRST DAY, THURSDAY, MAY 30TH—MORNING SESSION.

THE Association was called to order by the President, DR. ETHELBERT CARROLL MORGAN, of Washington, who delivered the

PRESIDENTIAL ADDRESS,

expressing the profound pleasure which he experienced in welcoming the Association to the national capital, the home of the scientific libraries, laboratories, and museums fostered and encouraged by a liberal government. The Association had wisely followed in the wake of numerous other scientific bodies, which make pilgrimages to our city and exert a healthy influence toward popularizing their special fields of scientific investigation. The noble work of this Association during its eleven years of existence has resulted in placing laryngology upon a substantial basis, and in demonstrating its truths and benefits alike to the profession and to suffering humanity. The outlook for laryngology was never brighter than at present.

The tenth volume of the "Transactions" is now in press, and in addition to the papers read at the last meeting of the Association, contains a table of contents of all the papers read to the Association since its organization.

An important amendment to the constitution, increasing the limit of active fellowship, comes up at this meeting. The present limit is fifty, and there are at present no vacancies.

Our library now contains nearly nine hundred separate titles. The librarian thinks that the collection would be more accessible if in charge of the Surgeon-General's Office, and recommends its donation to that library.

The Association has lost no members by death since the last meeting.

After some suggestion in regard to the social features of the annual meetings, the President closed by reiterating the assurance of his heartfelt appreciation of the goodwill and friendship which influenced the Association in selecting him as the President of this distinguished body.

The President then read the report of a case of

REMOVAL OF A SUPERNUMERARY TONSIL,

with specimen and drawings.

The patient, a male, aged twenty-six years, vigorous and otherwise healthy, came under observation September 7, 1886, with what he feared was malignant disease of the pharynx. The growth was first discovered four years previous. It had occasioned considerable pain, especially after smoking. During the past two months the growth had rapidly increased in size, and the pain had become of a shooting character, extending to the ears, larynx, and top of the head. Examination revealed a pendant tumor between the right palatine folds near the uvula and protruding beyond their borders half an inch. The tumor was as large as a small almond. Its color, as well as that of the pillars, was a dusky red. Slight engorgement of the cervical glands appeared to exist. The patient's mother had died of cancer of the breast, and he felt convinced that the growth was malignant. Local and general treatment having no effect, the tumor was excised and the raw surface cauterized with the galvano-cautery. In ten days the wound had healed. The patient was recently examined and there has been no recurrence, now four years after the operation. The specimen removed was examined by Dr W. M. Gray, microscopist to the Army Medical Museum, who stated that its structure was identical with that of a faucial tonsil which had undergone hypertrophy. The location and microscopic characters of this tumor, as well as the history of the patient prior to and subsequent to operation, proves that this was a hypertrophied accessory or supernumerary tonsil, an exceedingly rare anomaly. A search of the literature had revealed only two other cases of a similar character, reported by Jurasz in 1885. In the first case the tumor was as large as a hen's egg, and was found to spring from the lower anterior portion of the right posterior pillar by a small and short pedicle. It was removed and found, on microscopical examination, to present the structure of a hypertrophied tonsil. In the second case the tumor was of the size of a hazel-nut, and attached below the right tubal prominence. The microscope revealed a structure similar to that of the faucial tonsil.

Conclusions.—1. The lymphoid follicles of the soft palate and pharynx are liable to be aggregated, resembling in arrangement the faucial tonsil. 2. The condition is exceedingly rare, since, excepting the so-called "pharyngeal tonsil," the author had found but one case reported. 3. These lymphoid follicles are also liable to hypertrophy. 4. Such hypertrophies probably occur oftener than is generally supposed. 5. The indications for operative interference in this condition are identical with those for the faucial tonsil.

DISCUSSION.

DR. D. BRYSON DELAVAN, of New York, thought that possibly cases of supernumerary tonsil were not so infrequent as was commonly supposed. Pedunculated tumors of the tonsil, which on examination show a fibroid structure, are not rare, and it may be that these are degenerated supernumerary tonsils; just as the tonsil may, from long-continued inflammation, become the seat of fibroid change.

DR. GEORGE W. MAJOR, of Montreal, Canada, read a paper entitled

THE RELATION BETWEEN FACIAL ERYSIPELAS AND ERYTHEMA ON THE ONE HAND, AND INTRANASAL PRESSURE ON THE OTHER.

The following cases were cited as showing that facial erysipelas may be produced by nasal conditions, particularly when they are productive of pressure.

CASE I.—A girl, aged twelve, came under observation in March, 1884, for the treatment of nasal catarrh. There was a general hypertrophic condition, with pressure of the middle turbinated body of one side against the septum. On the cheek bone of the same side there was a red patch of erythema, which had existed for five months. Treatment of the nasal condition by scarification, puncture, and galvano-cautery was followed by disappearance of the erythematous rash, and it has not returned.

CASE II.—A child, four years of age, was seen in February, 1885, suffering with facial erysipelas, commencing on the bridge of the nose and extending to the cheeks. It had already lasted five days, and was not disposed to yield to treatment. Both nostrils were occluded by swelling. All treatment directed to the relief of the erysipelas was suspended, and attention directed to the relief of the nasal condition. In twenty-four hours the erysipelas had disappeared.

CASE III.—In the winter of 1884, a boy, aged twelve, the subject of recurring attacks of erysipelas, was seen with an attack involving the nose and cheeks. Nasal injections were alone used, and the erysipelas disappeared in thirty-six hours.

CASE IV.—February, 1889, a female, aged fifty-six, presented herself with an erythematous patch on the left cheek. This had lasted four months. There was swelling of the left turbinated bone, which pressed against the septum. Under treatment of the nose the erythema disappeared in the course of a week. Six other cases were alluded to in which the same connection was seen.

DISCUSSION.

DR. J. O. ROE, of Rochester, N. Y., had seen a number of cases of erythematous rash due to the nasal trouble. A case recently seen was that of a girl, aged twenty-three.

There was a very red erythematous patch on the face, associated with blebs. She had been treated by various physicians without benefit. In both nares the middle turbinated bodies pressed firmly against the septum. This was relieved, and there was immediately a subsidence of the erythematous trouble. He, however, could not admit that erysipelas is due *per se* to the intranasal trouble. He held that erysipelas was an infectious disease due to a distinct germ. The presence of erosions in the nasal cavity would render the patient more liable to become infected.

Dr. J. N. Mackenzie, of Baltimore, Md., said that the relation between erythema of the nose and face and intranasal trouble had been recognized centuries ago in the times of Willis, and by Sylvius. He himself had seen many cases of this kind, but he had never seen true erysipelas due to this cause. So-called facial erysipelas seems to be comparable to an accentuation of the act of blushing—a sort of chronic blush.

Dr. William H. Daly, of Pittsburg, Pa., was not a believer in the theory of intranasal pressure. The evils referred to pressure are really due to intranasal turgescence. The condition of erythema is nothing more than a condition of hypernutrition, due to a permanently dilated and enlarged blood-supply. He believed that the term chronic facial erysipelas is a misnomer.

Dr. F. I. Knight, of Boston, Mass., remarked that in these cases of erythema of the nose and face he always looked for neurosis, and very often found it. Where the trouble has been relieved, the affection of the skin has disappeared.

Dr. D. Bryson Delavan, of New York: I have seen several of these cases, and in three or four the erysipelatous attacks have been severe. One, a girl, aged seventeen, had recurrent attacks of severe erysipelatous swelling from the alæ of the nose extending over the cheek. These recurred at intervals of two or three weeks. There was marked turgescence of the nasal nervous membrane. This was treated topically, and with the subsidence of the catarrhal trouble the attacks of erysipelas disappeared.

Dr. Samuel W. Langmaid, of Boston, Mass., read a paper entitled

A CASE OF ACUTE MULTIPLE ADENITIS (SEPTIC?), ŒDEMA OF THE LARYNX, WITH SPONTANEOUS CURE.

The reader was called to see a lady, aged forty, who had been sick for seven days, under the care of an irregular practitioner. The patient was found restless, with an anxious expression, breathing with difficulty, and with a dry, croupy cough. There was no lividity of the face, but it was stated that during the preceding twenty-four hours there had been danger of strangulation. The submaxillary glands, as well as those in the region of the neck, were much swollen. Temperature, 99°; voice fairly loud and clear; no enlargement of the tonsils; nothing unusual in the naso-pharynx. With the laryngoscope a tumor, apparently as large as a filbert, was seen occupying the posterior arytenoid space. The anterior third of the vocal cords could be seen approximated and scarcely moving during respiration. I learned that the throat had not been examined until four days after the commencement of the attack. As the patient was breathing fairly well it was decided to do nothing. If necessary, the tumor in the larynx was to be incised. A few hours later something was felt to break in the throat, and a free mucoid discharge took place. Three hours later nothing could be seen but the erect epiglottis, with muco-purulent matter welling up. There was a continued discharge, but the relief to breathing was not complete. There had been also the discharge of half an ounce of pus. The discharge continued for several days, and the patient gradually recovered.

It was thought that the case was in all probability due to diphtheria, the evidence of which had passed away when the author examined the throat. The patient stated that at the commencement of the illness the throat had been sore, and that on one side she had noticed red spots, on which there had been a white covering.

Dr. William C. Glasgow, of St. Louis, Mo., followed with a paper on

AN ŒDEMATOUS FORM OF DISEASE OF THE UPPER AIR-PASSAGES.

The paper described an œdematous form of disease which had been epidemic around St. Louis for some two years. During the existence of this affection there has been a disturbance of the ordinary catarrhal throat troubles. In all cases of this disease there is found a pale, œdematous condition of the fauces. This is a solid œdema. A peculiar glistening appearance is at times very marked. In the majority of cases the soft palate is the seat of the œdema. At times the nasal mucous membrane is found in the same condition. The epiglottis and different portions of the larynx may be involved. In some cases the true cords are markedly œdematous. A swollen condition of the veins, particularly the pallatine veins, is present. This sometimes causes purpura-looking spots, and the mucous membrane appears mottled; in two cases these purpura-looking spots had been seen in the trachea. In one case enlarged veins were seen on the true cord. In some cases ulceration occurs. In some cases, in addition to œdema, there were patches of exudation in different parts of the throat. These, when removed, leave a bleeding surface. The symptoms of the disease and the appearance of the throat preclude the diagnosis of diphtheria. In six cases spots of mycosis were seen. Glandular enlargement of the neck is quite frequent. In two cases suppuration occurred.

The symptoms are constitutional and local. The affection occurs suddenly in persons of previous good health. There is languor and weakness, and general pains throughout the body. Headache is present, usually frontal, sometimes occipital. In many cases it is simply a dull, heavy feeling; in others it is an intense, violent, throbbing pain. Pain in the back, in the region of the sacrum, is a characteristic symptom. Fever is present in varying degrees. In the exudative cases the disease commences with chill followed by fever, and the temperature may reach 105° F. This soon passes off and we have a subfebrile condition remaining, possibly with a temperature of 101° F. This continues a short time, and then there is a return to the normal temperature. When there is simply œdema, the temperature scarcely ever rises above 101–102° F. This remains for only twelve hours, and during the remainder of the attack the temperature is normal. The pulse is always rapid, soft, and compressible. There has been no exception to this noted. The pulse ranges between 90 and 110 per minute. Profuse sweating is often present, especially during the night. It may be localized.

The local symptoms vary with the part of the throat involved. Sometimes they are prominent, sometimes they are wanting. Hemorrhages are common. They are usually slight, but recur frequently.

This is a constitutional disease due, the author believes, to some change in the blood, exactly what he was unprepared to say, but probably due to micro-organisms. He thought that the disease described was nothing more than influenza, the same influenza which has been described so often, particularly by Graves. The disease has not been limited to the Mississippi valley, for the speaker had seen cases of it from all parts of the country.

The treatment is very simple. The system must be saturated with benzoate of sodium. Under this remedy the affection subsides in a few days or hours. If left to itself, it may continue for weeks and even months.

DISCUSSION.

Dr. W. H. Daly, of Pittsburg, Pa., had seen a number of cases similar to those described. He did not consider the condition as one of œdema, but rather as a subacute inflammatory condition of the mucous membrane.

There was a sufficient number of these cases, which had thin and superfical diphtheritic patches in various parts of the fauces, to warrant him in considering the disease of a diphtheroid character. This view was confirmed by the subsequent occurrence of glandular enlargement in nearly all the cases.

Dr. J. C. Mulhall, of St. Louis, Mo., confirmed the statements of Dr. Glasgow from his own experience with the disease in St. Louis, and reported a case in which the affection had recurred three times.

Dr. S. H. Chapman, of New Haven, Ct., had seen cases similar to those reported, but agreed with Dr. Daly that they were rather of a diphtheritic character. In one case the disease attacked a child aged seventeen months. In the same family was a boy, nine years of age, with well-marked diphtheria. The first thing noted in the case of the child was a dense swelling of the submaxillary gland. There was great prostration and some fever, temp. 100° to 102° F. The swelling increased until it extended from the jaw to the clavicles. There was hoarseness and difficulty of breathing, which daily increased. By the seventh day it had increased so much that deep incisions were made into the gland, but no pus was found. A tube was then inserted into the larynx and allowed to remain four days. The child during this time was kept alive by rectal alimentation. At the end of thirteen days the swelling began to diminish. The knife was again used and a quantity of pus discharged. The child recovered.

Dr. C. E. Sajous, of Philadelphia, Pa., referred to a case of this disease which occurred in a young man living on a farm in New Jersey, twenty miles from any neighbors, and who had not been exposed to diphtheria. The throat presented small, white patches, not resembling the yellowish, leathery membrane seen in diphtheria. Slight œdema of the soft palate was also present. The temperature was high throughout the entire course of the disease. There was incessant pain in the back and in one limb. After trying a number of remedies, he was placed upon benzoate of sodium.

Dr. W. C. Glasgow, of St. Louis, Mo., remarked that he had at first regarded these cases as diphtheritic. The membrane in them is adherent. It can be torn away, but a bleeding spot is left. Applications made it worse. If left to itself, it gradually grows thinner and thinner until it resembles a white, pearly patch. Diphtheritic membrane does not pursue such a course. The glandular enlargements always occur, even where there is no exudation. He did not think that anyone would assert that this œdema was diphtheria.

Dr. W. H. Daly, of Pittsburg, Pa., read a paper entitled

Some Discursive Remarks Based Upon a Few Observations of the Intimate Relations of Chronic Disease of the Upper Air-Tract and Neurasthenia.

His experience had led him to believe that there was an intimate relation in conditions of the intranasal cavities and neurasthenia in some of its forms. This view was based upon the study of twenty-five cases. In these cases removal of the nasal trouble was followed by relief of the neurasthenic condition, no special treatment being directed to the general condition.

Discussion.

Dr. J. O. Roe, of Rochester, N. Y., said that most of the members had seen many such cases, and they illustrate the effect that a constant local irritation will have upon the system. A constant nagging of a local irritant will sooner or later produce a depressed condition of the system.

Dr. F. W. Hinkel, of Buffalo, N. Y., remarked that before we could admit that neurasthenic condition could be the result of any nasal lesion as the sole cause, a careful analysis of all the constituent conditions would be required.

Dr. S. W. Langmaid, of Boston, Mass., thought that often the nasal trouble was the result of the neurasthenia. It often happens that operative interference fails to relieve the nasal condition because the neurasthenia is not cured.

Dr. C. E. Sajous, of Philadelphia, Pa., was inclined to support rather vigorously the view of Dr. Daly. In a number of cases he had observed that there were fluctuations in the nervous condition according as the local disease improved or became worse. In one case of neurasthenia associated with deviated septum, correction of the displacement was followed by improvement in the nervous condition. The operation, however, failed to be permanent, and with the return of the deviation the neurasthenic condition recurred, to again disappear with a more thorough operation upon the septum.

Presentation of Instruments.

Dr. Samuel Johnston, of Baltimore, Md., referred to the ease with which the mouth and nose could be washed out by means of an ordinary seltzer bottle filled with soda-water, a rubber tube being attached to the delivery pipe.

Dr. J. O. Roe, of Rochester, N. Y., exhibited œsophageal bougies, made of hard rubber, with a flexible tip of soft rubber. Also jewellers' saws in frames, suggested to overcome the objection of flexibility in the ordinary Bosworth saw. Also a powder-blower with reservoir.

Dr. E. Carroll Morgan exhibited an instrument to pull the return forward in applying the galvano-cautery to the pharyngeal tonsil.

Afternoon Session.

Dr. John N. Mackenzie, of Baltimore, Md., read a paper on

Some Points in the Pathology and Treatment of Diseases of the Nasal Pharynx.

The following conclusions were presented: 1. The nasal pharynx is, in quite a large proportion of individuals, extremely sensitive to reflex-producing stimulation. 2. The areas chiefly involved are the posterior portions of the turbinated erectile tissue, and various points along the upper and posterior portions of the nasal pharynx. 3. In consequence of this extreme sensitiveness, a local pathological process, which in many persons would give rise to no reflex neuro-vascular changes, may awake a host of neurotic phenomena referable not only to the region primarily involved, but also to other and even remote organs of the body. These may include cough, asthma, and various neuralgic affections; or the local structural lesion may be the starting-point of various sympathetic affections of the respiratory tract. 4. That these classes of naso-pharyngeal neuroses are explicable on the same general principle laid down in the article on "Neuroses of the Nose," and the pathology of the nasal and post-nasal affections is therefore one and the same. 5. That the treatment should be carried out according to the general directions laid down in the article just mentioned. 6. That when morbid processes originate in the pharyngeal tonsil, attention should not be directed to the bursa alone, but an endeavor should be made to extirpate the tonsil as far as possible in its entirety. 7. That while a favorable prognosis cannot be safely predicted by treatment of the bursa alone, extirpation of the pharyngeal tonsil often affords a most favorable prospect in long-standing cases of post-nasal trouble.

Dr. D. Bryson Delavan, of New York, read a paper entitled

Observations upon the Condition known as Adenoid Hypertrophy at the Vault of the Pharynx, and the Methods used for its Removal.

A case was described in which, with each acute attack of catarrhal trouble, there would be enlargement of the adenoid tissue of the vault of the pharynx, forming a large

tumor. When the attack passed away the hypertrophy disappeared.

The author then referred to the methods of operation and the accidents which might occur. As the operation was attended with considerable pain, he suggested the employment of anæsthesia. He had in a number of cases employed chloroform with satisfactory result, the object being to avoid the profuse mucoid secretion which is apt to follow the use of ether. Where chloroform is used, the operation is performed with the patient on his back.

DISCUSSION.

Dr. F. H. Hooper, of Boston, Mass., reported a case of a young lady who came to him with acute coryza, and in whom he found a large-sized adenoid of the vault. After the attack subsided the adenoid almost entirely disappeared. In order to avoid error the post-nasal probe should be always used. With it conditions not apparent to the eye may be recognized. He had never seen serious hemorrhage follow operations for the removal of this tissue. In operating he first removes all that is possible with the post-nasal forceps, and completes the removal with the finger-nail. He had never used chloroform. The amount of secretion after the use of chloroform varies very much in different cases.

Dr. Harrison Allen, of Philadelphia, Pa., advocated the use of the finger as a means of detecting these post-nasal affections. To examine the case thoroughly requires the use of an anæsthetic. In the treatment of adenoid hypertrophy it is better to remove all the diseased tissue at one sitting under ether than to remove it in portions at different times.

Dr. J. C. Mulhall, of St. Louis, Mo., held that for practical purposes the pathology of the pharyngeal tonsil was exactly the same as that of the faucial tonsil. In operating he had applied cocaine thoroughly to the pharyngeal wall and soft palate, to avoid the disagreeable sensation caused by the scraping of the forceps against the healthy pharyngeal wall, and had succeeded very well.

Dr. F. I. Knight, of Boston, Mass., related a case of acute hypertrophy of the faucial tonsil, in which the surgeon performed tracheotomy preparatory to removing the tumor. When he came to operate, he found that the growth had disappeared.

Dr. William E. Casselbury, of Chicago, Ill., referred to the importance of thoroughly eradicating these growths. In two cases in which portions of the mass had been left, the reflex symptoms, while greatly lessened, continued to recur. In two cases he had attempted to use the mirror during operation. To do this he pulled the soft palate forward by two rubber bands, passing through each nostril. In one case he succeeded to a certain extent, but in the other failed. This procedure, however, greatly facilitated the operation. In order to prevent the passage of blood into the larynx he was in the habit of bending the head forward at intervals so as to allow the escape of the blood.

Dr. J. N. Mackenzie, of Baltimore, Md., as a rule operates without anæsthesia, removing a portion of the mass every day or every other day, continuing the operation for a week or ten days. He had seen very little pain from the operation. There is one point in regard to the nature of this so-called adenoid. He had examined a number of these growths under the microscope, and they do not differ from papillomatous growths. There is also in addition a true adenoid growth, this is more difficult of removal than the former.

Dr. F. H. Hooper, of Boston, Mass., read a paper

EXPERIMENTAL METHODS OF STUDYING THE ACTIONS OF THE INTRINSIC MUSCLES OF THE LARYNX.

The author exhibited the apparatus which he had employed in studying the effect of stimulation upon the internal thyro-arytenoid, the lateral crico-arytenoid, and posterior crico-arytenoid muscles. The larynx of a dog is quickly excised and the mucous membrane removed, and the muscles subjected to electrical stimulation.

Dr. F. I. Knight, of Boston, Mass., read a paper on

DYSPHONIA SPASTICA.

The speaker briefly reported the four cases of this affection which he had seen in the last seven years. He regarded the condition as rare. There is probably a spasmodic action of the muscles of phonation, or respiration, or both, giving rise to a high-pitched jerking voice. The prognosis is unfavorable. The object of the paper was to elicit reports of other cases.

DISCUSSION.

Dr. G. W. Major, of Montreal, Canada, had seen one case of aphonia spastica, and two cases of dysphonia spastica. In none of the cases was benefit obtained by treatment.

Dr. S. W. Langmaid, of Boston, Mass., had reported one case in which treatment was unsuccessful. The patient, when he had to use his voice, prescribed for himself a little whiskey, and this answered temporarily. There seems to be no change in the voice since the affection first came on, fifteen years ago.

Dr. D. Bryson Delavan, of New York, said that in one case coming under his observation, the patient was able to talk tolerably well after fortifying himself with a stimulant. This patient seemed to improve under local treatment to the larynx and vocal training, but the treatment could not be continued.

Dr. C. E. Bean, of St. Paul, Minn., had seen one case two years ago. Various methods of treatment had been employed without benefit. The voice is now the same as at the commencement.

Dr. Rufus P. Lincoln, of New York, read a paper on

RECURRENT LARYNGEAL GROWTH.

The patient had come under the care of the late Dr. Elsberg twenty four years ago. Dr. Elsberg first operated by the intro-laryngeal method, but could not remove the growth. Twenty-two years ago he did laryngotomy and removed the growth. The microscopical examination made at that time was unsatisfactory. There was no further trouble until a short time ago, when the growth recurred. Dr. Lincoln recently removed the tumor, which, upon microscopical examination, proved to be a papilloma.

Adjourned.

Friday, May 31st—Second Day—Morning Session.

Dr. T. Amory DeBlois, of Boston, read a paper describing

SOME OF THE MANIFESTATIONS OF SYPHILIS OF THE UPPER AIR-PASSAGES,

and exhibited drawings showing the conditions which he had found.

DISCUSSION.

Dr. F. H. Bosworth, of New York, referred to the necrosis of bone which occurs in syphilitic ulcerations. He did not believe that syphilitic ulcerations extended from one part to an adjacent part. Such ulceration is due to the breaking down of a gummatous deposit, and does not extend beyond the limits of the original gummatous deposit. The necrosis of the bone he held to be due to the interference with nutrition of the bone caused by the original deposit and that after the breaking down of the gummatous infiltration has taken place the ulceration is kept up by the necrosed bone, and treatment should, therefore, be directed to this point. He agreed with the reader of the paper, that potassium iodide was to be employed until the disappearance of the lesion, and that mercury should be used subsequently. Operative interference should be postponed until the syphilitic disease was well under control.

Dr. C. C. Rice, of New York, said that in these cases there was cicatrization and contraction above the visible adhesions, so that after the adhesions are freed, the results, as regards phonation and respiration, are not what would

be expected. This contraction in the post-nasal pharynx requires to be stretched in order to obtain good results.

In regard to operations: In one case where there were adhesions, and where there had been no syphilitic manifestation for many years, he separated the adhesions with the galvano-cautery. The ulceration which followed took on an unfavorable character, and continued to spread despite constitutional and local treatment.

DR. J. N. MACKENZIE, of Baltimore, protested against the too vigorous removal of diseased bone from the nasal passages. It frequently happens that more is pulled out than is desired, and sometimes from dangerous regions.

DR. WM. H. DALY, of Pittsburg, objected to the use of the galvano-cautery in tissues of the low vitality of syphilitic tissues. He believed that the galvano-cautery was a much abused useful instrument. He felt satisfied that better results could be obtained in the fauces, in the nose, in the larynx, in any operation, by using a sharp cutting instrument and allowing as free hemorrhage as is consistent with good judgment. The freer the hemorrhage within certain limits, the more certain is there to be immunity from septicæmia, and rapid union.

DR. CHAS. H. KNIGHT, of Boston, read a paper entitled

NOTE ON THE GALVANO-CAUTERY IN THE TREATMENT OF HYPERTROPHIED TONSILS.

This paper was supplementary to one read two years ago. The galvano-cautery cannot be satisfactorily used in young children, and in them the guillotine is preferable. In older children and adults the galvano-caustic point will prove of service. The galvano-loop was especially considered. With this the operation can be done at one sitting. The portion removed by the loop does not indicate the real extent of the operation. A portion of the remaining tissue sloughs, so that the operation with the loop is better than with cutting instruments. There seems to be very little more pain with the galvano-loop than with the guillotine. The former operation is, however, more disagreeable, on account of the odor of burning flesh.

DISCUSSION.

DR. T. A. DEBLOIS, of Boston, had used the electrolytic needle with good effect. Under cocaine, the pain of the procedure is very slight. Half a dozen punctures each day will in a short time produce great diminution. This method is used only in adults. In children the tonsils are very apt to diminish in size without treatment.

DR. C. E. SAJOUS, of Philadelphia, had frequently used the galvano-point, but had to make as many as eighteen or twenty punctures in order to obtain satisfactory results. After the second visit the patient expresses very little objection to the operation. The galvano-point is useful in the treatment of enlarged tonsils, especially where the density is not great. Here the cicatricial contraction assists in reducing the size.

DR. WILLIAM H. DALY, of Pittsburg, believed that in the normal throat, no portion of the tonsil extended beyond the line of the half-arches, and in abscission of the tonsil our object should be to restore the throat as nearly as possible to its normal condition. This cannot be thoroughly done with the tonsillotome, but the operation must be completed with forceps and bistoury.

DR. F. H. BOSWORTH, of New York, could see no reason for treating this condition by means of eighteen or twenty punctures, when the whole trouble could be removed in a few seconds by a very simple operation.

DR. C. C. RICE, of New York, believed that there are a few cases in adults, where there has been frequent attacks of tonsillitis and the tonsils are greatly congested, where the galvano-cautery is of service.

DR. JOHN O. ROE, of Rochester, read a paper entitled

THE TREATMENT OF DISEASED TONSILS WHEN UNATTENDED WITH HYPERTROPHY.

The conditions referred to are of marked clinical importance, but their consideration is ignored by writers upon these subjects. The most common form of disease of the tonsil is hypertrophy, and in children it is rare to find any other form. During adolescence the tonsils may diminish in size, but they do not return to their normal condition. The small tonsils in adults have often followed hypertrophy. This is a point in favor of the removal of enlarged tonsils. The two forms of disease of the tonsil to which attention was called were, first, chronic disease of the crypts and lacunæ, and, second, fibroid degeneration of the stroma of the organ, the cicatricial form of the disease. The first is the result of chronic follicular catarrh of the tonsil, and is usually associated with chronic follicular catarrh of the pharynx. The treatment of these conditions is important, not only on account of the disease itself, but also because they are the source of recurrent trouble, and may cause reflex symptoms. Local applications are practically useless. The galvano-cautery, which is useful in the treatment of hypertrophied tonsil, may be employed here, but is not as efficient as it is in the former condition. The treatment par excellence is ablation with the knife. The diseased crypts may be laid open and cauterized with chromic acid or fused nitrate of silver. Excision is, however, the best plan. It is rarely advisable to attempt removal of the whole mass at one time, on account of the adhesions to the pillars. The use of cocaine lessens pain and hemorrhage. In every instance in which the speaker had employed excision, the cure had been perfect, with entire relief from the attendant symptoms.

DISCUSSION.

DR. H. L. SWAIN, of New Haven, reported a case in which recurrent attacks of swelling of the lingual tonsil were caused by the presence of hard masses in the faucial tonsil. The attacks were subdued by treatment of the crypts, by cutting into them with the galvano-cautery and thoroughly cauterizing their interior.

DR. J. SOLIS-COHEN, of Philadelphia, had seen many cases of spasmodic cough due to nothing but the presence of these masses in the crypts and lacunæ of the tonsil. These had been found not only in enlarged, but also in apparently contracted tonsils. It is sometimes necessary to produce some gagging so that the posterior portion of the tonsil presents, in order to discover this condition. In enlarged tonsil the best treatment is probably excision, but in these atrophied tonsils he had pressed the matter out with a blunt scoop, and then applied a simple astringent consisting of creasote, gr. j., iodine, gr. j., potassii iodide, gr. v., and glycerine, ʒ j. If this does not answer, he cuts the crypts, open with scissors and scrapes them as thoroughly as possible. This affection is not as thoroughly appreciated by the profession as it should be. He had seen cases where cough, existing for five to ten or more years, had been permanently relieved by treating this condition.

DR. WILLIAM H. DALY, of Pittsburg, referred to cases in which the patients were really sick as the result of these lacunæ becoming filled with cheesy matter.

DR. F. I. KNIGHT, of Boston, described a case of long-continued irritative cough, in which the removal of a cretaceous mass, as large as a pea, from a crypt of the tonsil, was followed by complete cure.

DR. SAND JOHNSTON, of Baltimore, referred to three cases in which the collection, instead of consisting of soft cheesy material, was hard, looking like spicules of bone, and adhered with great intensity. These bodies were not limited to the tonsil, but were also found on the lower part of the fauces and on the post-pharyngeal wall.

DR. HARRISON ALLEN, of Philadelphia, stated that he had referred to this condition in a paper published in 1882. The solid matter is retained in the crypts. This pressure is often produced by the anterior fold. Sometimes the secretion has gotten out of the tonsil, but is still retained behind the fold. More frequently these masses are beneath the tonsil, under an adventitious membrane.

Dr. J. Solis-Cohen, of Philadelphia, read a paper entitled

A CASE OF SARCOMA OF THE THYROID GLAND.

The case was one of sarcoma of the thyroid gland, with pressure on the right sympathetic nerve; unilateral tonic spasm of the laryngeal muscles; intermittent clonic spasm of the muscles of the opposite side. There was stenosis from the pressure of the tumor. For this tracheotomy was performed. This afforded relief for a number of months. Hemorrhage occurred twenty months later, but was controlled without much difficulty. Gradually marked disturbance of the two pneumogastrics supervened, and there was great interference with respiration. It was accidentally discovered that any irritation of the mucous membrane of the trachea would relieve the dyspnœa, and at once the lividity of the face would disappear. This effect was readily produced by touching the posterior wall of the trachea with a bent wire passed through the tracheotomy tube. The patient died of exhaustion.

Adjourned.

At the invitation of the President the afternoon was devoted to an excursion to Mount Vernon.

Saturday, June 1st—Third Day—Morning Session.

Dr. C. C. Rice, of New York, read a paper entitled

SOME UNUSUAL MANIFESTATIONS OF TUBERCULOSIS OF THE LARYNX.

The first unusual manifestation referred to was where syphilis and tuberculosis of the larynx coexist. Here the lesions of one process mask those of the other. Here the prognosis depends upon which is the more active condition; this combination is more common than is generally supposed, and probably some cases of cure of supposed tuberculosis should be placed under this head. A second unusual manifestation is the engrafting on the tuberculous process of a new tissue, rendering the diagnosis difficult. This new tissue may be of two forms, either a granulation tissue or a papillomatous growth. The third condition was adhesive inflammation at the anterior ends of the vocal bands. This must be rare, as the tubercular process shows little tendency to cicatrization and healing. It is liable to occur only when the cords are immovable and there is general proliferation of tissue. The last condition referred to was one in which the tubercular deposit in one arytenoid was the only manifestation of the disease in the larynx, the remaining parts of the larynx being perfectly normal.

DISCUSSION.

Dr. W. H. Daly, of Pittsburg, was satisfied, from his experience in three or four cases, that in some instances tubercular ulceration of the larynx may be cured. In these cases there was no evidence of syphilitic disease, and in at least some of them the tubercle bacilli were found. Recovery has followed the use of alkaline sprays and inhalations, with the free use of iodoform. He believed that tuberculous ulceration of the larynx might occur without evidences of tubercular deposit elsewhere.

Dr. J. C. Mulhall, of St. Louis, thought that there might be a catarrhal ulceration of the larynx, and that this was a curable condition. He did not think that it would be easy to prove that tubercular disease of the larynx was ever primary, although it is sometimes the first sign of the condition. In tubercular ulceration of the larynx he had used pure lactic acid and had seen the ulceration heal, but he could not say that he had ever seen life prolonged to any appreciable extent.

Dr. F. I. Knight, of Boston, had not the slightest doubt that tubercular ulceration of the larynx does get well. He had seen such ulcers heal under alkaline sprays and iodoform, and more especially under lactic acid. He thought that it was possible to have the tubercular disease of the larynx as a primary affection, but in the majority of cases careful examination will reveal evidences of disease of the lung. He did not regard changes in the respiratory murmur and in respiration as the most important signs of early phthisis. He placed more reliance upon the localized râles which are heard on coughing. In order to develop this sign the patient should not inspire immediately before or after the cough, but should cough from a rest. He had seen but a few cases in which he regarded the disease as primary in the larynx.

Dr. M. E. Casselbery, of Chicago, reported a case in which he found catarrhal ulcerations of the larynx. These readily healed under cleansing treatment, and there had been no return of the ulceration during a period of two years.

Dr. J. N. Mackenzie, of Baltimore, thought that the question of the possibility of the existence of primary tubercular disease of the larynx had been settled by examinations, upon the post-mortem table, where, in a few cases, careful examination of the body revealed tubercular deposit nowhere but in the larynx. While a tubercular ulceration of the larynx may heal, this by no means indicates the cure of the disease. I have seen the coexistence of syphilis and tuberculosis in the larynx several times, and it is difficult to say which is the syphilitic and which the tubercular ulceration. The only test is that of treatment. He had never seen what could be called catarrhal ulceration of the larynx. In regard to treatment, he thought that more harm than good was produced by the employment of harsh measures. There is a form of ulceration which occurs in the later stages of phthisis, principally near the bifurcation of the trachea, which is probably due to the corrosive action of the sputa.

Dr. W. C. Glasgow, of St. Louis, believed that tubercular ulcers of the larynx were never healed. He had seen cases of ulceration of the larynx heal under treatment, but he did not consider these to be true tubercular ulcerations. These have healed under simple treatment. He had used with great satisfaction, during the past two years, the peroxide of hydrogen in the treatment of such ulcerations, and under its use there is rapid healing. He did not believe in primary tubercular disease of the larynx. In all the cases that he had seen, there had been more or less disease of the lungs. In true miliary tuberculosis of the larynx, he had always found some evidence of disease in the lung, and these cases he thought never recovered. He had seen cases of catarrhal ulceration of the larynx.

Dr. S. Solis-Cohen, of Philadelphia, read a paper entitled

THE OCCASIONAL TOPICAL USE OF SOLUTIONS OF NITRATE OF SILVER IN THE TREATMENT OF CHRONIC LARYNGITIS.

The cases reported were not due to nasal disease or obstruction; nor were they those in which all topical treatment is unnecessary. Where indigestion, constitutional disease, or diathesis have been present, these have received due attention. It was simply of topical applications for the relief of local conditions that he spoke. All have encountered cases of chronic laryngitis, especially in singers, clergymen, lawyers, etc., in which, after all discoverable sources of irritation, local or general, have been removed, and approved topical treatment suited to the individual case has been faithfully tried, for a longer or shorter time, improvement takes place to a certain point and then stops. Perhaps all visible evidences of disease, except an irregular, pinkish striping of the vocal bands have disappeared, or perhaps there would be a faint uniform coloration, or may be only a loss of lustre, but something there would be that persisted, and that prevented the patient from resuming with comfort full use of the voice in singing or speaking, or perhaps even in ordinary conversation.

It is in such conditions as these, the last obstinate remnants of the disease, that he had derived considerable satisfaction from the topical use, by sponge, cotton-wad, or brush, of weak solutions of silver nitrate, about ten grains to the ounce, applications being made every day,

for two or three days, until some congestive reaction is produced; after that at longer intervals. In the course of treatment, too, in some cases before reaching the last stage above described, I have found recovery apparently hastened by occasionally substituting stronger solutions of silver nitrate, forty to sixty grains to the ounce, for the iodized glycerine, tannin, tar, or other routine application. A visible increase in congestion immediately follows the use of the silver solution, but this passes off quickly, and at the next visit great improvement is usually manifested. These applications are made once in about two or three weeks, according to circumstances.

Dr. C. E. Bean, of St. Paul, read a paper entitled

TUBERCULOSIS OF THE TONGUE.

The author described two cases of tuberculosis of the tongue, one in a male and the other in a female. In both the disease had made extensive progress when they came under observation, and no operative measures seemed warrantable. In both there was well-marked involvement of the lungs. Death occurred in both cases a short time later. Attention was called to the differential diagnosis between tuberculosis, carcinoma, and syphilis. Carcinoma is to be excluded by the absence of glandular enlargement, and of the lancinating pains peculiar to that disease. The question of syphilis can only be determined by the history and by the effect of antisyphilitic remedies.

Dr. J. C. Mulhall, of St. Louis, read a paper entitled

THE LOCAL TREATMENT OF DIPHTHERIA.

The method of treatment which he suggested was based upon the following considerations: 1. That diphtheria is a germ disease. 2. That the specific microbe, in the majority of cases, selects the tonsils. 3. That, unless checked by treatment, the colonization of these germs results in local putrefactive changes with subsequent involvement of the general system. 4. That implication of the larynx, or of the nasal passages, increases the mortality. 5. That the disease is acutely adynamic. It had occurred to him that in this disease it would be better to wash out the throat than to spray it. This is accomplished by means of an ordinary syringe, and in this way the throat can be washed out without difficulty. The patient should be kept in the recumbent position, the head being brought to the edge of the bed. This procedure is repeated every hour during the day, and at no time is a longer period than three hours allowed to elapse. The only solution that he has used has been carbolic acid with compound solution of iodine. The water is frequently saturated with boracic acid.

The post-nasal space requires careful attention. In every case of diphtheria the nasal cavities should be kept sterile from the first. Where it is certain that the nasal cavities are not affected, the insufflation of a non-irritating, antiseptic powder may be sufficient. Where there is uncertainty, or where it is certain that infection has taken place, the nasal cavities are to be washed out with a weaker solution of the same kind—not more than a teaspoonful for each nostril. For this purpose he recommended a small glass syringe with a bulbous extremity, to prevent injury to the nose. After cleansing he frequently resorts to solvents, and has obtained the best results with papoid. In laryngeal diphtheria, inhalation is the only practicable method. The inhalation of the vapor from slacking lime should not be forgotten. In several cases of laryngeal diphtheria he had obtained good results by placing the patient in a small room which had been fumigated with sulphur, and by keeping water, to which has been added pine-tar and turpentine, constantly at the boiling point.

DISCUSSION.

Dr. W. C. Glasgow, of St. Louis, believed that diphtheria is a blood disease rather than a local affection, and that the only objects in local treatment are cleanliness, disinfection, and loosening of the membrane. One remedy which he had used with advantage was the peroxide of hydrogen by spray. It seems to act by lifting up the membrane by the formation of gas. He considered the constitutional treatment as the most important, and he thought the bichloride of mercury and benzoate of soda were the most successful remedies. With these he uses very simple local treatment. In the cases of severe local manifestations the method described by Dr. Mulhall would be valuable.

Dr. D. Bryson Delavan, of New York, referred to the value of the bichloride and cyanide of mercury, which he had used for ten years in the treatment of diphtheria.

Dr. W. H. Daily, of Pittsburg, had on previous occasions recommended the use of calomel in the treatment of this affection, and he thought that it was as efficient as a local agent as it was active as a constitutional remedy. He believed that calomel in large and frequently repeated doses—two, three, four, or five grains to children one and a half to two years of age—exerted a valuable therapeutic effect. He thought that a large part of the effect was from the local action upon the diphtheritic poison.

Dr. Harrison Allen, of Philadelphia, referred to the value of trypsin as a solvent for the diphtheritic membrane.

Dr. F. Whitehill Hinkel, of Buffalo, read a paper entitled

SOME MANIFESTATIONS OF LITHÆMIA IN THE UPPER AIR-PASSAGES.

The influence of lithæmia and allied conditions upon the upper air-passages has received little attention in laryngology, as is shown by the scanty literature extant upon the subject. There is a distinction to be made between distinctly gouty sore throat and that due to lithæmia or some allied condition. The subjects of the latter may never have attacks of true gout, nor irregular manifestations of it—indeed, as a rule, they are not so affected. The term lithæmia is elastic in its application to cases, varying from extreme digestive and nervous disturbances to almost normal health; consequently its manifestations in the upper air-passages are not sharply distinguished, nor are they typical or pathognomonic. One of the most characteristic manifestations is a patchy or streaked irregular congestion of the mucous membrane of the larynx and pharynx. In the former case a dry, explosive cough accompanies; in the latter, uneasiness or positive pain is referred to the sides of the throat, occasionally extending to the ears. These cases are notably irritated and made worse by stimulant applications. Local sedatives and general antilithic treatment give the best results. Occasionally, acute naso-pharyngeal catarrh is a manifestation of an exacerbation of the lithæmic tendency. Alkaline and diluent medication, with proper diet, give more relief than local treatment. Obstinate relaxation of the nervous plexuses of the turbinated bodies in some individuals appears associated with lithiasis. Such cases stand operative—caustic—applications badly, and receive little or no benefit from them. Some of these cases are much improved by antilithics and general hygiene. Others are intractable on account of uncontrollable lithæmic tendencies.

OFFICERS FOR ENSUING YEAR.

President—Dr. J. M. Mackenzie, Baltimore; *1st Vice-President*—Dr. Edgar Holden, Newark; *2d Vice-President*—Dr. C. E. Bean, St. Paul; *Secretary and Treasurer*—Dr. C. H. Knight, New York (No. 20 West Thirty-first street); *Librarian*—Dr. T. R. French, Brooklyn; *Council*—Drs. Franklin H. Hooper, Boston; George M. Lefferts, New York; Frederick I. Knight, Boston; D. Bryson Delavan, New York; *Representative on the Committee of the Congress of American Physicians and Surgeons*—Dr. Harrison Allen, of Philadelphia.

The following were elected to membership: Drs. William E. Casselbery, Chicago; H. L. Swain, New Haven.

The Association then adjourned to meet in Baltimore, the time of meeting to be determined by the Council.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

LEPROSY AND ITS PREVALENCE—MODERN PROVISIONS FOR THE CARE OF LEPERS—CLOSING MEETINGS OF THE MEDICAL SOCIETIES—MR. HUTCHINSON ON THE CLINICAL USES OF RARE DISEASES—ENLARGEMENT OF THE THYROID GLAND IN SIX MEMBERS OF ONE FAMILY—THE NEW BY-LAWS OF THE COLLEGE OF SURGEONS AND THE COMING ELECTION TO THE COUNCIL.

LONDON, May 12, 1889.

THE subject of leprosy is one of which the interest is on the increase both among the profession and the public. In spite of the attention which has been devoted to the subject, there is as yet no general consensus of opinion in the profession, or rather, among those members of it who are qualified to express an opinion on the matter, as to the contagiousness and the inoculability of the disease. The Leprosy Committee of the College of Physicians, in their recent report to the College, urged that a full and careful scientific investigation should be made by the Government. The extent to which the disease is prevalent was shown in a striking manner at the last meeting of the Epidemiological Society, when Dr. P. S. Abraham read a paper on "Leprosy," and exhibited a map of the world in which those regions where leprosy is more or less prevalent were colored dark. Dr. Abraham's paper literally bristled with statistics, and can therefore hardly be briefly summarized in a very few lines; but the facts and figures he brought forward would tend to show that the disease is becoming more common, and that it is more frequently met with in countries in which hitherto leprosy has not been endemic. The various leper hospitals and asylums in different parts of the world were referred to. It was encouraging to learn that in Norway the milder forms of the disease are regarded as being, to some extent, amenable to treatment. A number of microscopic specimens were shown, illustrating the morbid changes found in the skin, nerves, liver, and other organs; the bacilli of leprosy (from the saliva of a leper) were also exhibited. Two leprous patients were also on view—one of each variety of the disease, viz., tubercular and anæsthetic leprosy respectively. Dr. Abraham objected to the former term as inaccurate, for the disease had no affinities with tuberculosis, nor could the growth in the skin be described as physical tubercles; "nodular" would be a better term. Dr. Pringle made an energetic speech, in which he referred to the increase of the disease in India. Formerly, he said, it was very common for lepers to be put to death, either by drowning, burying them alive, or in other ways. This had now been forbidden by the Government, on whom it was therefore incumbent to provide proper means of caring for and segregating lepers. The sexes should be kept apart in leper asylums. It had been said that this could not be done, but it was carried out in some asylums and an instance was mentioned. Dr. Pringle incidentally remarked that leper settlements had their origin in the association of lepers together for mutual protection. The further discussion of the paper was deferred to the next meeting of the Society.

As the winter wanes, so does the interest in the meetings of the various societies. Most of them will shortly cease to meet for the present season. During the last week two have held their final meeting, viz., the Medical Society of London and the Harveian Society. At the former, the annual conversazione marked the close of their labors for the present season. In the course of the evening an address was given by Mr. Jonathan Hutchinson on "The Clinical Uses of Rare Diseases." He said that the diseases which presented the most apparent peculiarity were often, if correctly understood, definite examples of evolution under ordinary laws. Many rare diseases were simply exaggerated or overgrown examples of common ones. Thus, for one case of Grave's disease which was so severe as to justify the diagnosis, there were probably twenty in which the condition threatened but never became complete. If it were true that many of the diseases accounted rare were simply exaggerated specimens of what was common, it was true of others that they revealed individual idiosyncrasies of exaggerated intensity. Xeroderma pigmentosum (Kaposi's disease) was a noteworthy instance of this; all examples of unusual freckling—perhaps all freckling whatever—denoted a minor form of Kaposi's disease. We might also learn something as to anatomical and physiological laws from the careful observation of rare cases. Thus he had met with three male patients in whom, while the urethral and anal sphincters were paralyzed, the power of copulation remained undiminished; a demonstration was thus supplied of what was agreed on by physiologists, viz., that the spinal centre for copulation was higher than, and distinct from, that which supplied muscular force to the sphincters and regulated micturition and defecation. The condition known as "dry mouth," since it was unattended by any other symptom, supplied a proof that there was a centre which controlled the function at once of the salivary glands and of all the mucous crypts and smaller gland organs which were found in the mucous membrane of the cheeks, palate, gums, and tongue. It was not unimportant to assert that there were absolutely no cases which were unique. However strange and bizarre the phenomena in any individual case, we had but to wait long enough to find their exact parallel.

The concluding meeting of the Harveian Society was a "Clinical Evening," being devoted to the exhibition of living patients and the discussion of their cases. A very interesting family group was shown by Mr. Jacobson, assistant-surgeon to Guy's Hospital. This consisted of a mother, aged thirty-seven, and five children, whose ages ranged from one to twelve. In all, the thyroid gland was enlarged. In the mother the enlargement had been so excessive as to cause serious interference with breathing and necessitate an operation. Thyroidectomy had been recently performed, and almost the whole of the gland removed; the patient was still wearing a drainage-tube. In the children the enlargement of the gland was less extreme, but, in view of its probable increase, the opinion of the Society was asked as to what measures would be desirable. Among the remedies (other than operative interference) suggested by those who discussed the case were the injection of acetic acid, inunctions of an ointment of the red iodide of mercury, and repeated blistering (small blisters the size of sixpence or a shilling).

The Home Secretary has approved, with certain modifications, of the new by-laws of the College of Surgeons, and it is therefore hoped that it will be possible to inaugurate voting by means of voting papers at the coming (July) election to the Council.

WHITE SPOTS IN THE RETINA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: I read with interest the two cases described by Dr. Valk in a recent number of THE RECORD, but do not think they are parallel ones to mine. The white dots in my case were beyond doubt in the retina, as shown by a close examination in the upright image, convex lenses of different strength being used to adjust the eye to the varying distance of the detached retina from the observer.

I find that Schweigger also mentions the occurrence of these spots in the detached retina as a rare condition, which he is inclined to ascribe to the presence of cholesterine.

Yours respectfully,

F. E. D'OENCH, M.D.

NEW YORK, May 25, 1889.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from June 2 to June 8, 1889.

MERRILL, JAMES C., Captain and Assistant Surgeon. By direction of the Acting Secretary of War, is detailed as a member of the Board of Medical Officers appointed by Par. 9, S. O. 108, May 10, 1889, from this office, to meet at the United States Military Academy, West Point, N. Y., on June 1, 1889, or as soon thereafter as necessary, to examine candidates for admission to the Academy, etc., vice Captain Frederick C. Ainsworth, Assistant Surgeon, hereby relieved as a member of the Board. Par. 4, S. O. 127, A. G. O., June 3, 1889.

OWEN, W. O., Jr., Captain and Assistant Surgeon. The leave of absence for seven days, granted in Orders No. 18, c. s., Fort Gibson, I. T., is extended twenty-three days. Par. 2, S. O. 67, Headquarters Department of the Missouri, Fort Leavenworth, Kan., May 29, 1889.

KEAN, JEFFERSON R., First Lieutenant and Assistant Surgeon. By direction of the Secretary of War the leave of absence granted in S. O. No. 48, May 13, 1889, Department of the Platte, is extended fifteen days. Par. 3, S. O. 129, A. G. O., June 5, 1889.

WALES, PHILIP G., appointed Assistant Surgeon with rank of First Lieutenant, from June 7, 1889.

DEWITT, THEODORE F., appointed Assistant Surgeon with rank of First Lieutenant, from June 7, 1889.

TEN EYCK, BENJAMIN L., appointed Assistant Surgeon with rank of First Lieutenant, from June 7, 1889.

Official List of Changes in the Medical Corps of the United States Navy for the week ending June 8, 1889.

PAGE, J. J. (retired), Assistant Surgeon. Granted one year's leave of absence, to leave the United States.

BAILEY, THOMAS B., appointed an Assistant Surgeon in the Navy, May 23, 1889.

BARBER, GEORGE H., appointed an Assistant Surgeon in the Navy, May 23, 1889.

ROTHGANGER, GEORGE, appointed an Assistant Surgeon in the Navy, May 24, 1889.

SMITH, GEORGE TUCKER, appointed an Assistant Surgeon in the Navy, June 3, 1889.

BAILEY, T. B., Assistant Surgeon. Ordered to the Receiving-ship Dale, at Washington, D. C.

BARBER, GEORGE H., Assistant Surgeon. Ordered to the Receiving-ship Vermont, at New York.

OGDEN, F. N., Assistant Surgeon. Ordered to examination preliminary to promotion.

BRYANT, P. H., Assistant Surgeon. Detached from Naval Hospital, Chelsea, and granted a month's leave of absence.

MAYO, H. O. (retired), Medical Director. Granted one year's leave of absence, with permission to leave the United States.

ELECTROLYSIS IN STRICTURE.—Dr. Fort read a paper at a meeting of the Academy of Medicine in Paris, on April 14th, on the treatment of urethral stricture by electrolysis, in which he stated that he had obtained very good results from this method, two cases treated by him in public a year ago being now well, and with no signs of a recontraction. The operation, he maintains, should be preferred to divulsion, dilatation, or cutting, even if it were always followed by a return of the stricture, since it is painless and devoid of danger.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending June 8, 1889:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	12	4
Scarlet fever	159	26
Cerebro-spinal meningitis	2	4
Measles	110	10
Diphtheria	147	41
Small-pox	0	0
Yellow fever	0	0
Cholera	0	0

BILLROTH'S ILL-HEALTH.—The visitor who has seen photographs of the celebrated surgeon in charge of this clinic, experiences rather a shock when Billroth himself appears. Instead of a man in full vigor, robust, and of iron constitution, as his pictures represent, he is quite the reverse. I am told that his dangerous illness of last year has wrought the change. His frame is large and muscular; the head partially bald and carried well forward, giving a decided stoop to his shoulders; the hair gray, and the full beard almost white as snow. He walks as though he had not yet recovered his strength. His speech is somewhat hesitating, and in so low a tone as to be heard only in the front rows of the amphitheatre. But it is his method which we most admire. There is still great steadiness of hand—every detail, it is easy to see, is within his control; so that with declining health and strength his mental faculties are not impaired. He is surrounded by a dozen bright and energetic assistants, to whom, as well as to most of the Vienna students, Billroth is a demigod. There is a somewhat Hebraic countenance, with a look of benevolence, compassion, and deep thought intermingled. —Vienna correspondence, *Occidental Medical Times*.

THE PROMOTION OF ILLEGITIMACY IN VIENNA.—In connection with the obstetrical department of the hospital, and in the hope that the system would prevent induced abortions among the lower classes, the following plan was adopted some years ago: Any woman can enter the hospital, masked or not, as she desires; be known only by a number; live according to one of three grades—the cheapest costing about thirty cents a day; be attended in labor by skilful accoucheurs, and leave the hospital when she desires, with or without the child. If without the child, it is given a number, by which the mother can reclaim it even after years. When not reclaimed, the child, if a boy, is brought up as a soldier; if a girl, as a nurse. The only condition required of the mother is the payment of the small living fee (thirty cents a day), and enclosing her name and address of friends in an envelope to the secretary of the hospital, which is only opened in the event of her death while in the hospital. If all goes well, on her departure from the hospital it is returned to her unopened. This plan has indeed decreased the abortions and increased the population of Vienna, but it has also removed another check on free intercourse—the fear of becoming pregnant.

CAPTAIN COOK'S RHEUMATISM CURED BY MASSAGE.—Dr. J. Werthner, of Lincolnville, Kan., writes: "Having been under the impression that massage was a comparatively recent and novel method of therapeutics, I was astonished and much interested while reading an account of Captain Cook's third voyage around the world, in 1777, to see the following: 'While stopping at Otaheite, one of the Society Islands, Captain Cook was freed from a rheumatic complaint, that consisted of a pain extending from the hip to the foot. Otoo's (the chief's) mother, his three sisters,

and eight other women went on board for the express purpose of undertaking the cure of his disorder. He accepted their friendly offer, had a bed spread for them on the cabin floor, and submitted himself to their direction. Being desired to lay himself down amongst them, then as many of them as could get round him began to squeeze him with both hands, from head to foot, but more particularly in the part where the pain was lodged, till they made his bones crack, and his flesh become a perfect mummy (!). After undergoing this *discipline* about a quarter of an hour, he was glad to be released from the women. The operation, however, gave him immediate relief; so that he was encouraged to submit to another rubbing down before he went to bed; the consequence of which was, that he was tolerably easy all the succeeding night. His female physicians repeated their prescription the next morning, and again in the evening; after which his pains were entirely removed and the cure perfected. This operation, which is called *romee*, is universally practised among the islanders; being sometimes performed by the men, but more generally by the women' ('Narrative of the Voyages round the World by Captain Cook,' by A. Kippis, D.D., F.R.S., etc.). The above is probably not unknown to some of the medical profession, but to many it will likely be new."

Beer Compared with Other Alcoholics.—For some years a decided inclination has been apparent all over the country to give up the use of whiskey and other strong alcohols, using as a substitute beer and other compounds. This is evidently founded on the idea that beer is not harmful, and contains a large amount of nutriment; also, that bitters may have some medical quality which will neutralize the alcohol which it conceals, etc. These theories are without confirmation in the observation of physicians. The use of beer is found to produce a species of degeneration of all the organs, profound and deceptive fatty deposits, diminished circulation, conditions of congestion, and perversion of functional activities; local inflammations of both liver and kidneys are constantly present. Intellectually a stupor amounting almost to paralysis arrests the reason, changing all the higher faculties into a mere animalism, sensual, selfish, sluggish, varied only with paroxysms of anger that are senseless and brutal. In appearance the beer-drinker may be the picture of health, but in reality he is most incapable of resisting disease. A slight injury, a severe cold, or a shock to the body or mind, will commonly provoke acute disease, ending fatally. Compared with inebriates who use different kinds of alcohol, he is more incurable and more generally diseased. The constant use of beer every day gives the system no recuperation, but steadily lowers the vital forces. It is our observation that beer-drinking in this country produces the very lowest kind of inebriety, closely allied to criminal insanity. The most dangerous class of ruffians in our large cities are beer-drinkers. Recourse to beer as a substitute for other forms of alcohol merely increases the danger and fatality.—*Scientific American.*

Slight Aortic Insufficiency.—Experiments were published recently by Dr. Timofejew, in which he showed that a very slight aortic insufficiency may exist without producing a diastolic murmur, but that here a distinct accentuation of the second sound can then be heard; he also found that with greater but still slight insufficiency, though a murmur is produced, this can be made to cease by diminution of the blood-pressure, either by venesection or by section of the spinal cord. These experimental observations are in full accord with the well-known clinical fact that an aortic bruit is sometimes temporarily much less pronounced than usual, and may even occasionally disappear. An interesting paper has just been published by Professor Carl Dehio, of Dorpat (*St. Petersburg Med. Woch.*, No. 50, 1888), in which he gives the details of a case which illustrates this variability of some aortic bruits very well. The patient was a student who had suffered from syphilis. At times he experienced severe pain in the region of the heart, accompanied by dyspnœa, headache, giddiness, and faintness. He had consulted several physicians, some of whom had detected a murmur, while others had declared there was none. Professor Dehio found at first, while the patient was sitting, merely some accentuation of the second sound, but as soon as he stood up a blowing murmur was audible over the whole of the body of the sternum synchronous with the second sound, and prolonged to the end of the diastole. After a time this became less and less perceptible, and finally vanished, but on the patient moving or working his arms about it reappeared. Tracings taken with a Dudgeon's sphygmograph showed that while the patient was in a recumbent posture, there being no murmur, the pulse, which was beating 80 per minute, was of a normal but weak character, with a slight distention-wave and a low blood-pressure, the secondary waves being only just perceptible. On standing up, the beats increased to 88 per minute, the bruit becoming then audible, the tracing assumed the character frequently observed in cases of neurotic cardiac palpitation, the pulse-wave being higher, but falling rapidly, and the secondary and tertiary waves being well marked. After considerable exertion, when the bruit was louder still, the beats being, however, only 76 per minute, the distention-wave was three times as high as when the patient was lying down, and it fell very quickly, being in fact the typical *pulsus celer*. It is seen that the bruit was dependent on the initial blood-pressure due to the force of the contraction of the left ventricle, rather than on the mean intra-arterial pressure, which was probably not increased, since, according to the researches of Riegel and of Wetzel, there is no increase in the mean pressure where the secondary waves become more pronounced. It is evident from the tracings that whenever the primary wave increased, the secondary waves increased also, and thus that while when the patient was in a recumbent posture there was but a gentle backward stream through the defective valves, yet upon a slight amount of exertion the velocity of this stream was greatly increased, and thus became capable of producing a murmur. This difference between a gentle and a rapid stream can be easily illustrated by compressing an india-rubber tube through which water from a cistern is flowing, when the murmur, which can both be heard and felt, is readily found to depend on the velocity of the water. Dr. Dehio remarks that he cannot well have mistaken a murmur of hæmic origin for a slight aortic insufficiency in this case, for the whole history, the dilatation of the heart, the occasional whistling character of the murmur, and the serious subjective sensations of pain and palpitation all point to organic mischief. Again, the insufficiency must, he thinks, be of slight extent, as the dilatation of the left ventricle was but very moderate, and as Duroziez's double bruit was not audible in the femoral arteries.—*The Lancet.*

Medical Reform in Turkey.—Dr. Morris J. Franklin (New York Medical University, 1858), medical missionary, writes from Safed, Syria, Turkey, under date of April 11, 1889, that he has just received an *Emir* or order from the Imperial Academy of Medicine of Constantinople that all medical practitioners must prove their qualifications and present their diplomas for registration at Constantinople, and that this edict is to be strictly enforced throughout the Empire. Dr. Franklin, who has been appointed Doctor of his municipality, and is vested with the powers of a censor, further says that, owing to the laxity of enforcement of this law (which was passed as a law twenty-eight years ago), the country has been overrun with charlatans from every quarter of the globe.

The Kidneys in Diabetes.—Fichtner points out that among the lesions observed in the kidneys of subjects of diabetes, glycogenic degeneration or infiltration of the epithelia of Henle's tubes is one of the most constant, but yet difficult of explanation (*The Lancet*). Changes in the cortex have been less frequently met with; some have

seen acute interstitial inflammation, leading even to granular kidney; others describe epithelial necrosis, especially in cases of diabetic coma, attributable to the action of acetone and diacetic acid. Fatty degeneration is described by various writers, notably by v. Frerichs and Ebstein, the latter meeting with marked fatty change and free fat between cells. Fichtner in two cases of diabetic coma found, in addition to the glycogenic degeneration of Henle's tubes, very marked fatty degeneration of the cortical epithelium, the fat-globules and particles being in each case regularly arranged along the periphery of the cells just beneath the basement membrane; and those tubules solely were affected which contained cloudy epithelium. The epithelia of other parts, as well as the glomeruli and the connective tissue, were apparently normal; and there was no indication of necrotic or inflammatory change. The absence of inflammation was remarkable, especially in one of the cases, which during life presented albuminuria and renal casts, and was therefore considered to be a case of chronic nephritis, with diabetes. The peculiar type of fatty change had been met with by Fichtner in a case of chronic nephritis following alcoholism, but in that case many tubules exhibited a more diffuse degeneration than the variety described. In cases of phosphorus-poisoning the cells are filled with fat-globules of various size and grouping. In seeking for an explanation of the lesion, he remarks that both these patients died comatose, and had the peculiar odor of the breath indicative of acetone and diacetic acid in the urine. Having regard to the previous observations of Albertoni and Pisenti, as well as of Ebstein, which point to the connection between epithelial necrosis in the kidney and the presence of these substances in the urine, it is highly probable that the special kind of fatty degeneration must be referred to these or allied bodies. If fatty degeneration occurs apart from coma, its cause must be found in the excess of sugar. The subject is open to experimental research, which may throw some light upon the subject of renal secretion.

THE LATE DR. FRANK W. ROCKWELL.—At a special meeting of the trustees of St. Mary's Hospital, New York, held May 7th, the following preamble and resolutions were unanimously adopted:

"*Whereas*, We have heard with profound regret of the sudden demise of Dr. Frank W. Rockwell, a most zealous and able member of our hospital staff, and whose untiring efforts and acknowledged professional skill in the special department of which he was chief have contributed largely toward the efficiency and wide reputation of our institution; and

"*Whereas*, By the death of Dr. Rockwell St. Mary's Hospital, which has been the recipient of his valued services since its organization, has sustained a grievous loss; the profession, of which he was a distinguished member, a high-minded, skilful, and conscientious surgeon, and the community at large a benefactor; therefore, be it

"*Resolved*, That, while regretfully testifying to his honorable record and unostentatious labors in the cause of suffering humanity, we deeply sympathize with his bereaved family and respectfully tender them our sincere condolence.

"*Resolved*, That the foregoing be incorporated in our minutes, and a duly authenticated copy thereof be forwarded to his family. (Signed) John Byrne, M.D., John J. Kiernan, James Clyne, Committee."

At the last meeting of the Hospital Faculty of St. Mary's General Hospital, New York, the following resolution was passed:

"The Hospital Faculty of St. Mary's Hospital desire to put on record their deep emotion at the death of their friend and colleague, Dr. Frank W. Rockwell. Dr. Rockwell died at the age of forty-six, on the very threshold of what is regarded as the intellectual prime by all civilized races. Yet he stood in the foremost rank of his profession, not only in the city of his residence, but throughout the country. That fact alone attests his intellectual stature. But those who knew him more intimately than by reputation knew that his character was a rare combination of the mental qualities which compel praise and the softer ones that win without the asking. Endowed with a marvellous capacity for absorbing information, so that he was at home in every branch of his profession; with a delicacy of touch and mechanical skill as an operator that met the requirements of the best surgical technique; with abounding and quick resources, and of excellent judgment, he had as well a gentle nature and a gentle manner, an omnivorous appreciation of humor and art and literature and the changing phases of nature. What better credentials than these can a man have to the esteem of his friends during life, and to their remembrance after death? Physicians though we are, accustomed to death and disease and their ravages and surprises at every turn, a death like this comes home to our bosoms, and we can only inadequately express to the widow of Dr. Rockwell our sorrow and the infinite sympathy that we feel for her and her children. William E. Griffiths, M.D., Landon Carter Gray, M.D., Committee."

CONSANGUINEOUS MARRIAGES.—The author of a recent work on this subject calls attention to the curious ideas which have been generally received in reference to the infecundity of, and physical degradation consequent on, consanguineous marriages. So far as the data given may be trusted—and it is hardly to be supposed that the author holds a brief on the opposite side—there is absolutely nothing to show that marriages between near kinsmen are lacking in fertility, or that they are peculiarly liable to give issue to deformed or diseased offspring. There is no lack of instances of enforced consanguinity, in the matter of marriage, in isolated communities, according to M. Huth, to disprove the assumption that physical degeneration is likely to result from the practice. An investigation into a number of unions between uncles and nieces, nephews and aunts, and cousins in the first and second degree, gives an average of children rather above than below the general average, though this is attributed to some extent to the comparatively early age at which such unions are generally contracted. Breeders inform us that the results are markedly in favor of consanguineous unions between healthy well-bred animals. Unions between men, or animals, of widely different varieties, on the other hand, have a decidedly injurious effect on the offspring, and beyond a certain limit are almost absolutely sterile. Mulattoes and the half-breeds of India and America are striking examples of the deterioration to which such racial disparity gives rise. The great point to bear in mind is that the union of individuals with the same morbid tendencies intensifies the taint, and that, too, quite irrespective of any consanguinity. The moral, according to the author, is that the reasons which have led to the prohibition of marriages within certain degrees of relationship are social, and not physiological.—*Medical Press and Circular.*

SUMMONING THE DOCTOR WITH A CANNON.—They have rather a curious way of summoning a doctor, when the services of one are required after nightfall, at Bedloe's Island, on which the big statue of Liberty stands, and as all communication with the mainland and Governor's Island is suspended during the night, a cannon is fired. This at once attracts the attention of the sentinels on Governor's Island, and a surgeon from the garrison is soon on his way to Bedloe's Island in a row-boat. In this way Dr. Pilcher was called the other night, and he arrived in time to present a fine boy to one of the officers stationed there.—*Boston Medical and Surgical Journal.*

SALICYLATE OF SODIUM IN PRURITUS.—Dr. Icard reports, in *La Gazette Médicale*, a case of obstinate pruritus, which had resisted a number of remedies, but was quickly relieved by the internal use of sodium salicylate in doses of forty-five grains a day.

EYE-STRAIN AS A CAUSE OF HEADACHE AND NEURALGIA.

WITH REMARKS CONCERNING THE PREVALENT FALLACIES RESPECTING THESE CONDITIONS.

BY AMBROSE L. RANNEY, A.M., M.D.,

PROFESSOR OF THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

SOME time since, I encountered in my reading the following extract from the pen of a great French philosopher:

"Nature fights with disease a battle to the death. A blind man armed with a club—that is, a physician—comes in to make peace between them. Failing in that, he lays about him with his club. If he happens to hit disease he kills disease; if he hits nature he kills nature."

There is in this charming piece of satire more than a single atom of truth.

In nothing is it better illustrated to-day than in the literature of medicine relating to neuralgias and headache.

There are undoubtedly more sufferers among the community at large from these two forms of paroxysmal pain than from any other morbid conditions. This statement is, I think, sustained by all carefully prepared statistics. The amount of literature which has lately been contributed to this subject would also indicate to the candid reader not only their great prevalence, but the peculiar intractability, in some cases, of these types of pain in spite of drugs.

A very large percentage, moreover, of victims to headache and neuralgia fail to disclose any positive evidences of actual disease, in spite of the greatest care in searching for a cause. The nerve-trunks affected, the brain itself, or its coverings, the heart, the lungs, the kidneys, the liver, the stomach, and the intestine, etc., seem in most cases to be capable of performing their normal functions, save when some temporary disturbance (not generally referable to any definite cause) occurs simultaneously with, or prior to, one of these paroxysmal attacks of pain. Such disturbances are too frequently regarded by various observers as of great significance, but to my mind clinical experience teaches us that they are to be classed rather as mere coincidences, or as a part of the attack itself.

We, as a profession, have yet much to learn respecting the remote effects of a disturbed nervous equilibrium upon the organs of the chest and abdomen.

We have also, in the light of modern physiology, much to unlearn, many inherent prejudices to overcome, many clinical conclusions to discard (that have grown upon us from defective habits of reasoning) before our patients can derive the full benefits of our own advancement.

If we start out, for example (as many physicians do), with the premise (generally an incorrect one) that every patient who has a disturbed stomach, a sluggish bowel, or clay-colored fæces prior to, or in connection with, a headache, owes his headache directly to his stomach, liver, or bowel, and must base his recovery upon some drug which shall re-establish their action, many patients will become imbued with ideas which may, perhaps, indefinitely postpone, or totally preclude, the opportunity of obtaining permanent relief by the removal of a cause not affected by drugs, and too often unsuspected by the patient.

Too many medical men ignore the fact to-day that an underlying cause exists in almost every case of intractable neuralgia or headache.

Yet they speak with assurance respecting the clinical significance of some slight draught of air; look for some trivial excess or error of diet as an important factor; condemn hastily, and on general principles, some acquired habit which has been tolerated by the patient for years without apparent injury (such as tobacco, for example); shift the responsibility from themselves upon that much-abused organ the liver; and in countless ways strike wildly about with their club of unscientific deduction (according to the French philosopher), hoping to kill a disease whose causes and nature they may not have carefully investigated.

A bad tooth, impacted wax within the ear, eyes with defective refraction, imperfectly balanced eye-muscles, an obstruction to the passage of air through one or both of the nasal cavities, some hidden rectal irritation, and many forms of pelvic disease too often remain unrecognized in many patients as factors in causing headache and neuralgia, while learned dissertations and useless medication are offered to the patient as a means of relief.

Hardly a day passes that I do not see some sufferer of this class in my office, who has passed through many years of periodical suffering from frequent headaches or persistent neuralgic attacks unnecessarily, simply because the exciting cause has either never been sought for, or investigated by imperfect methods and with too little care.

Headaches and neuralgias may be discussed under three prominent classes—the toxic, organic, and reflex varieties. Of these, the latter is the most common.

There is, unquestionably, a certain proportion of individuals (where headache is a marked symptom) that owe their suffering to some abnormal condition of the blood.

Among this class of causes we must recognize the poisoned blood of Bright's disease, the saccharine blood of diabetes, the decrease of red and white corpuscles observed in anæmia and leucocythæmia, the blood-changes produced by malarial poisoning, and some typical cases of poisoning by lead, mercury, arsenic, alcohol, etc.

It must be acknowledged, however, that sufferers from these forms of headache are comparatively infrequent, when contrasted with the thousands in which no evidence of actual disease can be discovered by scientific means. Yet sufferers of this class are too commonly encountered to justify the omission of a careful examination of the urine in any individual case—an excretion whose constituents decide quite conclusively the existence or non-existence of any typical morbid state. If deemed necessary, the blood also, and other fluids of the body can be subjected to scientific investigation. It is certainly a culpable oversight, in any case where headache exists, to neglect a careful analysis of the urine.

Again, there is encountered a class of patients who suffer from more or less obstinate and intractable headache and neuralgia as a result of organic disease of the brain or its coverings.

Certain forms of spinal disease are likewise apt to create more or less excruciating forms of pain that might easily be, and too often are, mistaken for neuralgia in some of its forms. These do not, however, as a rule, cause headache, if the spinal nerves are alone involved.

In the cerebral and spinal types of cases the ophthalmoscope becomes a valuable instrument, since it will

often show alterations in the retina or "disk." Moreover, other symptoms referable to the power of motion, sensation, or the special senses are very apt to exist and to point directly to the presence of organic disease of the nerve-centres.

While it is advisable, therefore, to exclude organic disease of the nerve-centres by appropriate tests employed for that purpose in every case of intractable headache or neuralgia, still it may be said that such cases constitute but a small proportion of those who seek medical aid for the symptoms under consideration in this paper.

Admitting, then, the fact that the presence of headache and neuralgia may, in some instances, be but a clinical evidence of organic disease, it is our manifest duty in every case to exclude, as far as it is possible to do so, the existence of organic disease in each individual case; or, if such be detected, to combat it by wise therapeutical measures. On the other hand, the comparative percentage of such cases is too small, and the possibility of other causes (as coexisting factors) too large, to justify us today in neglecting to take into account in any case the various types of reflex disturbance to the nervous centres which clinical experience has shown may both modify and cause severe cranial pain or neuralgic paroxysms.

I have deemed it wise to insert these few remarks as a preface to my paper upon the "Relationship of Eyestrain to Headache and Neuralgias," for the following reasons:

1st. Because the profession at large has not, in my opinion, woke up thoroughly to the fact that a very large percentage of headaches and neuralgias can be relieved, and often radically cured, without drugs.

2d. Because most of the later contributions to this subject have very clearly demonstrated that the authors of these papers even are singularly apathetic to facts that have already passed beyond the limits of unsupported theory, and are being recognized by many of the eminent scientists of our day.

3d. Because remarkable cures of headache and neuralgia are being daily forced upon professional notice, which have been brought about solely by the removal of some source of reflex irritation, such, for example, as decayed or ulcerated teeth, a deflected nasal septum, and errors of focus or of the muscular adjustment of the visual apparatus.

4th. Because any new therapeutical measure meets with far less opposition than does the introduction of a scientific method of search for obscure causes of disease. The public has been educated to want drugs, and doctors to rely too much upon them.

5th. Because many of the older views respecting the underlying factors of disease are destined to be overthrown by many of the later discoveries in physiology, bacteriology, etc.

6th. Because all views not in accord with popular belief are constantly being misrepresented, misunderstood, and misapplied by those who either do not wish to know them (from personal prejudice), or who have had little practical experience in the methods advocated. The history of medical progress is replete with examples of violent opposition to all innovations—such, for example, as vaccination, Listerism, ovariotomy, etc.

7th. Because scientific methods of precision require a special training of mind and eye and hand, not commonly required of undergraduates in our medical schools.

Not long since I received a letter from a physician (who had asked of me some suggestions respecting the ocular treatment of a case that had proven intractable to all medical agents) in which he says:

"What troubles me now is the fact that I am not sufficiently posted on the diagnosis of the eye to use your valuable information. I feel very much inclined, however, *to go it blind on the case I spoke of, and give it a trial.*"[1]

Such an evident misconception of the experience, skill, and care required in the diagnosis and treatment of an error in the focus or a defective muscular adjustment of the eyes requires no further comment from me.

For some years past it has been my custom to examine repeatedly, and with care, the visual apparatus of every patient sent to me for the relief of headache and neuralgia. I have already published, from time to time, many cases where this line of research has been followed by marked and permanent benefit.[1]

I deem it worthy of remark, in this connection, that less importance is being attached to-day than formerly to the clinical determination of modifications in the calibre of the blood-vessels of the brain.

The conditions known as "cerebral congestion" or "cerebral anæmia" of certain authors who have written extensively upon headache and neuralgia are very often the results of underlying factors.

Their existence (as has been claimed) may sometimes be revealed by the ophthalmoscopic examination of the vessels of the retina and confirmed by the effects of nitrite of amyl upon the patient; but when so, they are probably to be regarded rather as an evidence of a functional derangement of the vaso-motor system of nerves than as permanent factors in headaches or neuralgias.

I have known many patients who have followed, with negative results, a prolonged course of treatment (by ergot, bromides, amyl, etc.) which was based upon the examination of the retinal vessels; and I have often seen them recover from their headaches and neuralgias without drugs when an anomaly of refraction or of the muscular adjustment of the eyes was corrected.

I would not be construed as denying that the blood-vessels of the brain might not have been abnormally dilated or peculiarly contracted in many of these patients at the time when their retinal vessels were examined; nor would I utterly reject the hypothesis that the retina sometimes affords us a valuable means of determining by our sense of sight the condition of the cerebral vessels in any given individual.

What I do mean to assert is this: That changes in the cerebral circulation (as is often observed in the case of a blush upon the cheek) may be caused by subtle nervous influences that ergot, bromides, nitrite of amyl, or other drugs will not arrest; that a classification of headaches or neuralgias which is based upon so variable a sign is unscientific; and that any line of medication which is directed toward this condition alone is very liable to be unsatisfactory both to the physician and his patient, sooner or later.

To illustrate this point I will mention a remarkable experience of my own that impressed me strongly at the time.

Some ten years ago, when almost in despair from continuous and intractable headache, and doubtful of my ability to long endure it, two oculists of equal prominence and ability were asked by me to examine my retinæ by means of the ophthalmoscope.

One diagnosed my condition as "typical nicotine poisoning of the retina;" the other discovered what seemed to him to be conclusive evidences of "congestion of the brain," that nothing but prolonged rest from work, in his opinion, could relieve. Neither suggested the detection of any "lateral" refractive error or the use of glasses. My sight was apparently perfect and unusually acute.

Subsequently the instillation of atropine into my eyes (which was used at my earnest solicitation) and the correction by proper convex glasses of a hypermetropia of 3.00 diopters (not previously suspected) restored me to health and comfort, as if by magic. A complete and immediate cessation of all pain for over nine months followed the correction of my refractive error; and for many years I have been almost entirely free from pain, in spite of continuous eye-work at my desk and elsewhere.

[1] Italics my own.

[1] New York Medical Journal, January, 1888; Lectures on Nervous Diseases, Philadelphia, 1888 (F. A. Davis, Publisher); Medical Register, Philadelphia, November 19, 1887.

A Tabulated Record of Fifty Consecutive Cases of Headache and Neuralgia treated exclusively by the Correction of Eye-strain.

Case.	Age.	Sex.	Condition.	Symptoms.	Duration.	Heredity.	Visual tests.		Treatment.	Remarks on Case.
							Refraction.	Muscular.		
1	50	M.	Married.	Sick-headaches (very frequent and severe). Asthenopia.	Since early childhood.	Headaches in all paternal ancestry and in brothers and sisters. Phthisis common among maternal ancestry.	R. + 0.75^s L. + 1.00^s + 0.50^c	Right hyperphoria, 2½°. Exophoria, 1°.	Full correction of refractive error by glasses. 1° prism for R. hyperphoria.	This patient is still under observation, as "latent" hyperphoria is suspected to exist. No headaches have occurred since the glasses have been worn. The muscular adjustment of the eyes will soon be rectified by a graduated tenotomy
2	26	M.	Single.	Sick-headaches. A peculiar nervous hesitancy of speech. Mental depression of a marked character. Mental weakness (since childhood). Extreme nervousness and excitability.	Since 12th year. do. do. do.	Father and two brothers have severe headaches. Ancestry are peculiarly nervous and excitable.	Manifest emmetropia. Atropine not used.	Esophoria, 15°. Homonymous diplopia, 3° (with red glass).	Graduated tenotomies of both interni.	Patient had to leave for the West. He refused atropine tests on that account. After the tenotomies the power of abduction was increased from 1° to 8°. No headaches have occurred since operation. Patient lately reports a great change in his general health and a sense of rest in his eyes never experienced prior to the operation. The mental power of this patient already shows marked improvement.
3	20	F.	Single.	Supra-orbital neuralgia. Frequent fainting attacks. Complete amenorrhœa. Melancholia. Dyspepsia. Asthenopia.	Since childhood. do. For 2 yrs. Since childhood. For 2 yrs.	Mother had frequent fainting attacks. One brother has severe headaches. Two cases of epilepsy on paternal side. Diabetes very common on maternal side.	R. + 0.50^s + 0.50^c L. + 1.25^s	Right hyperphoria, 6°. Exophoria, 1°.	5° R. hyperphoria prism given.	Patient is still under treatment, but has been almost entirely relieved of her neuralgic paroxysms by the glasses ordered. She is much less depressed and has had no fainting attacks. A graduated tenotomy is to be performed shortly, to correct the hyperphoria.
4	30	M.	Married.	Occipital headache. Insomnia. Hesitancy in speech. Fainting attacks. Dyspepsia. Asthenopia.	Since childhood. do. do. 2 years.	Father is a dyspeptic and rheumatic. Mother is at times insane. Headaches are a family trait. One uncle was insane. One cousin had epilepsy.	R. + 1.50^s L. + 1.25^s	Right hyperphoria, 2°.	Patient was given for constant wear: R. + 1.50^s L. + 1.25^s	This patient's attacks were often accompanied by symptoms of *petit mal* He is still under observation, but has experienced great relief from his headaches since his glasses were ordered. No attacks of loss of consciousness have occurred since the glasses were prescribed.
5	53	M.	Married.	Severe headache, frontal and occipital. Insomnia of an intractable type. Prostatic and urethral irritation, causing the patient great anxiety and discomfort.	Since childhood. 2 years. 2 years.	Father had severe headaches. Mother and two sisters had phthisis.	R. + 1.50^s L. + 1.50^s + 0.50^c	Right hyperphoria, 4°. Esophoria, 1°.	Patient was given + 1.50^s 1½° prism in each eye to correct right hyperphoria.	This patient expresses himself as almost completely cured of headache and insomnia by his glasses alone. His business engagements have thus far prevented a radical step toward the correction of his hyperphoria. His prostatic neuralgia has been very decidedly relieved without any local treatment thus far.
6	28	F.	Married.	Neuralgia (very severe and chiefly of the supra-orbital and occipital types).	Since 5th year.	Father is very nervous. Mother has neuralgic headaches. Paralysis in paternal ancestry. Phthisis on maternal side.	R. + 0.75. L. + 0.75.	Left hyperphoria, 6°. Esophoria, 0°–6°.	Graduated tenotomy of right inferior rectus.	This patient reports that a great change for the better has occurred since the operation. Her neuralgic attacks have been decreased 75 per cent. and her physical condition is greatly improved.
7	13	M.	Single.	Headache (in frontal and occipital regions). Has been almost constant and is often accompanied by vomiting.	3 years.	Headaches and eye-defects are common on the maternal side. One paternal uncle has headaches, and another incipient ataxia. Rheumatism is a family trait on paternal side.	R. + 0.25. + 0.50^c L. + 0.25. + 0.50^c	Left hyperphoria, 3½°.	Given for distance, + 0.50^c Graduated tenotomy of right inferior rectus.	This patient has had no headache for several months since the operation. He still suffers from occasional gastric disturbances. There is reason to suspect some "latent" hyperphoria in this case, which may demand further operative work.
8	43	F.	Married.	Sick-headaches (so frequent and severe as to unfit the patient for household duties for the past ten years).	Since childhood.	....	R. + 1.00^s L. + 1.00^s	Right hyperphoria, 5½°. Esophoria, 2°–8°.	Given for constant wear, + 1.00^s Graduated tenotomy of left inferior rectus.	This patient reports a very marked decrease of her headaches since the operation, and a remarkable increase of physical strength. The last report states "that she can endure fatigue better than for many years and has headaches only at long intervals." Further operative work will probably be demanded in this case.
9	26	F.	Single.	Supra-orbital and occipital neuralgia. Asthenopia (of many years' standing). Dyspepsia and vomiting.	Since 12th year. For 6 yrs. past. For many years.	.....	R. − 2.25^s L. − 1.00^s	Right hyperphoria, 2°. Esophoria, 14°.	Given for constant wear: O. D. − 2.25^s O. S. − 1.00^s Graduated tenotomies of left inferior rectus and of both internal recti.	This case has proved to be a very difficult one to treat. She had homonymous diplopia, together with a marked hyperphoria. Her ability to use the eyes in sewing and reading has been greatly improved, and her neuralgic paroxysms and vomiting have been markedly benefited, but not arrested as yet. She is still under observation, and further operative work will have to be done later on.
10	30	F.	Married.	Frequent and severe sick-headaches. Asthenopia (of a severe type). Nervous prostration (lasting for many months).	Since 9th year. Several years. 5 yrs. ago.	Father and sister are subject to sick-headaches. Maternal grandmother has neuralgia.	R. + 1.25^s L. + 1.25^s	Right hyperphoria, 5°. Esophoria, 15°.	Graduated tenotomies of left inferior rectus and of both interni.	The last reports from this patient give assurances of almost a perfect cure. Her headaches have disappeared. Her asthenopic symptoms are subsiding fast. Her physical strength is almost entirely restored.
11	14	M.	Single.	Frequent and protracted headaches—last most of the time; are frontal and occipital. Asthenopia. Obstinate constipation.	2 years. 4 years. Since childhood.	Phthisis and epilepsy in both paternal and maternal ancestry. One brother has epilepsy.	R. + 0.75^s L. + 0.50^s + 0.25^c	Esophoria, 12°. Left hyperphoria, 7°.	Graduated tenotomies on both interni and right inferior rectus.	This case is still under observation and has proved to be quite intractable. The muscular anomalies of the orbit have been extreme, and sufficient time has not elapsed for the patient to get the full benefits of their correction. He reports that he "has much less asthenopia and headache, and is now able to study with little distress."

A Tabulated Record of Fifty Consecutive Cases of Headache ana Neuralgia treated exclusively by the Correction of Eye-strain.—Continued.

Case.	Age.	Sex.	Condition.	Symptoms.	Duration.	Heredity.	Visual tests. Refraction.	Visual tests. Muscular.	Treatment.	Remarks on Case.
12	30	M.	Single.	Headaches (chiefly frontal). Melancholia. Constipation.	18 mos. do. 6 years.	Mother died of cancer; father of typhoid fever; maternal aunt died of phthisis. Headaches very common on both sides.	R. + 0.25. − 1.00ˢ L. Emmetropia.	Esophoria, 7°.	Given for constant wear: + 0.25 = − 1.00ˢ for right eye. Graduated tenotomy of both interni.	This patient had been under the care of many prominent physicians without obtaining any relief from drugs. He writes me as follows: "I pass many pleasanter days now than for many years past." His improvement, when last seen by me, was very apparent. His headaches are less frequent and severe.
13	26	F.	Married.	Sick-headaches (very severe and frequent). Asthenopia. Weakness in arms and legs, also fainting attacks. Severe pain between the shoulder-blades.	Since childhood. For past 3 years. For past 3 years. For past 3 years.	Father died of heart disease. Mother had severe headaches and vertigo. Maternal grandfather was insane.	R. + 0.50ˢ L. + 0.50.	Right hyperphoria, 4°. Esophoria, 2°.	Graduated tenotomy of left inferior rectus, 1° prism for balance of right hyperphoria still remaining.	This patient had been under constant medical care for years before I saw her. Her symptoms were generally attributed to uterine trouble, but all treatment so directed proved unavailing. Although her eye-muscles are not yet perfectly adjusted, she has experienced a very marked change for the better. Her headaches and asthenopia have been decreased over 75 per cent., and the pain in the back has almost entirely ceased.
14	46	M.	Married.	Sick-headaches. Nervous prostration. Nervous weakness and morbid fears after any unusual strain.	Since childhood. 9 yrs. ago. Several years.	Father had severe headaches and died of Bright's. Mother died of cerebral softening. One brother died of "neuralgia of brain." Mental diseases on paternal side are common.	R. + 1.00. + 0.25ˢ L. + 1.00. + 0.25ˢ	Esophoria, 6°.	Given for constant wear: + 0.25ˢ = + 0.25ˢ Graduated tenotomy of left internal rectus.	This patient still has an occasional headache, but at long intervals. He expresses himself, in a late communication, as delighted with the marked change which has occurred. His physical condition has improved rapidly since the operation.
15	28	F.	Single.	Constant headache. Pain in the back—which has proven very rebellious. Asthenopia. Physical weakness (to such an extent as to render walking almost impossible). Insomnia.	3 years. Since 14th year. Since childhood. 10 years.	Headaches and neurasthenia very common on maternal side.	R. + 0.50. L. + 0.50.	Esophoria, 15°. Homonymous diplopia of 2° (with red glass). Right hyperphoria, 4°.	Graduated tenotomies of both interni, and of the left inferior and right superior recti.	This patient wore a plaster jacket for over a year for her spinal pain; and was also treated for uterine conditions, without any relief to her symptoms. Her ocular conditions proved to be very complicated and difficult to fully correct. She now is almost entirely free from spinal pain—has only occasional headaches—and is able to walk several miles each day.
16	16	F.	Single.	Constant headache (without any intermission). Chorea, which had practically disappeared before I saw the patient.	Since 8th year. In childhood.	Father has had several attacks of *petit mal*. Mother had sick-headaches and nervous prostration. Mother's family is very nervous. Paternal grandmother and uncle died of phthisis.	R. + 1.00ˢ L. + 1.00ˢ	Left hyperphoria, 7¾°, most of which was latent. Exophoria, 9°.	Graduated tenotomies of right inferior rectus, left superior rectus, and both externi.	A marked improvement in this case has been effected, but the patient still has headache at times, which is always intensified by close application of the eyes.
17	36	F.	Married.	Headaches, always after any fatigue, as shopping. Asthenopia.	For some years.	Mother died of phthisis. One sister is a victim to headaches.	R. + 1.25ˢ L. + 1.25ˢ	Exophoria, 3°.	Given for constant wear, + 1.00ˢ	This patient made a complete recovery by the aid of cylindrical glasses. The last report I received was that she "had been for several months absolutely free from headache."
18	30	M.	Married.	Sick-headaches (these headaches lasted 2 or 3 days in each week). Indigestion. Constipation.	5 years. do. do.	Father died of gastric trouble. One brother has headaches.	R. + 4.50ˢ + 0.25ˢ L. + 4.50ˢ	Esophoria, 8°.	Given for constant wear, + 2.50ˢ Graduated tenotomy of right internal rectus.	Patient left for his home in Kansas City, Mo., with instructions to report the results of treatment. Although many months have elapsed no report has been received.
19		F.	Married.	Supra-orbital neuralgia. Insomnia. Marked twitching of the eyelid.	12 years. do.	One sister has neuralgia.	R. + 0.75ˢ + 0.75ˢ L. + 1.00ˢ + 0.50ˢ Reads No. 1 Jaeger's type with + 1.00ˢ	Esophoria, 2°.	Given for constant wear: O. D. + 0.75ˢ O. S. + 0.50ˢ For reading, + 1.00ˢ was added to each of the cylinders.	This patient has reported that she is "completely cured, and is in perfect health." She has had no pain for over a year.
20	25	F.	Single.	Sick-headaches. Asthenopia. Constipation.	Since 15th year. One year. do.	Mother had headaches when young. Phthisis on maternal side.	R. − 0.50ˢ L. − 0.50ˢ	Esophoria, 6°.	Given for distance, − 0.50ˢ	This patient refused surgical treatment of her esophoria. She would not tolerate prisms, as they caused distress. She returned to the West without any benefit.
21	44	F.	Married.	Neuralgia. Nervous prostration (3 attacks). Chronic constipation.	20 years. do.	One brother and one sister died of phthisis. Phthisis common on paternal side.	R. + 1.75ˢ L. + 1.75ˢ	Esophoria, 3°.	Given for constant wear: + 1.00ˢ; for reading + 1.50ˢ Graduated tenotomy of left internal rectus.	The last report from an oculist to whom I intrusted this case, after her departure from New York, gives assurance of a decided physical improvement, but not, as yet, a radical cure of the neuralgia. A latent hyperphoria is suspected to exist, which is still under his observation.
22	27	M.	Single.	Headaches (very severe, occurring 3 or 4 times a week).	Since 15th year.	Mother died of cancer.	R. − 2.00ˢ L. − 2.00ˢ	Esophoria, 4°.	Ordered for constant wear, − 1.50ˢ, combined with 1° prism, base out, in each eye.	This patient had gone over six months without a headache when last heard from. He expresses himself as "astounded at the magical change which followed the use of glasses."
23	33	F.	Single.	Sick-headaches (very severe and frequent). Morbid and uncontrollable fear of company, sudden noises, etc. Very emotional. Twitching of the eyeball. Difficulty in raising the upper lids.	Since early childhood. 4 years. do. do. do.	Father died of phthisis. Phthisis common in paternal ancestry. One maternal uncle died of phthisis.	R. + 0.50ˢ + 0.50ˢ L. + 1.00ˢ	Exophoria, 5°. Left hyperphoria, 4°.	Given for constant wear: O. D. +0.50ˢ = + 0.50ˢ O. S. + 1.00ˢ Graduated tenotomies of both externi and right inferior rectus.	This case was one of great interest to me. She had been under the care of several oculists, who had simply corrected the astigmatism of the right eye. Her mental condition caused serious alarm. The results of treatment have been very gratifying. Patient has entirely recovered control of her emotions, and has but few headaches. She often passes many consecutive weeks without any pain.

A Tabulated Record of Fifty Consecutive Cases of Headache and Neuralgia treated exclusively by the Correction of Eye-strain.—Continued.

Case.	Age.	Sex.	Condition.	Symptoms.	Duration.	Heredity.	Visual tests.		Treatment.	Remarks on Case.
							Refraction.	Muscular.		
24	45	M.	Married.	Neuralgic headaches (very severe and almost constant). Vertigo (after looking intently at any object). Dyspepsia and acid stomach. Confusion of thought. Insomnia.	Since early childhood. 30 years. Since childhood. 15 years. do.	Father had headaches. Mother died of brain disease. Everyone of his maternal ancestry suffer severely with headache and neuralgia. One brother died of brain disease. Two sisters suffer terribly with headache.	Emmetropia, Presbyopia, + 1.25s	Esophoria, 12°. Left hyperphoria, 1°.	Graduated tenotomies of both interni and right inferior rectus.	Patient was a physician. He had regarded his condition as incurable. A remarkable heredity existed as regards headache, neuralgias, dyspepsia, and brain diseases. He is now practically well. An occasional headache and a weak stomach indicate that the eye-strain is not entirely removed. He still shows some esophoria at times.
25	31	M.	Married.	Neuralgic headaches (very severe and only controlled by large doses of morphine). Habitual constipation. 3 per cent. of sugar in the urine (analysis of Dr. G. T. Elliott, of New York).	6 years.	Mother had severe neuralgic headaches.	R. + 1.50s L. + 1.50s	Esophoria, 5.° Left hyperphoria, 3°.	Given for constant wear, + 0.50s Graduated tenotomies of right internus, and left superior rectus.	This case was pronounced by Dr. G. T. Elliott, of New York, as "one of typical diabetic headache." Without any drugs, his sugar was reduced to a half of one per cent. within a few weeks, by the relief of abnormal muscular tension in the orbit. The neuralgic attacks were totally arrested for a time, but the patient has thus far failed to allow of a complete restoration of muscular equilibrium.
26	29	F.	Single.	Severe sick-headaches. Asthenopia.	Since childhood. do.	Father suffers with neuralgia. One brother suffers with severe headaches.	R. + 3.00s L. + 2.50s	Exophoria, 6°.	Given for constant wear: O. D. + 1.50s O. S. + 1.00s Graduated tenotomies of both externi.	Very marked benefit, for a time, in regard to headaches and asthenopia. Further correction of a "latent" esophoria that disclosed itself after the tenotomies were advised; but the patient has thus far failed to report at my office.
27	28	M.	Single.	Constant dull headache. Habitual constipation. Cold hands and feet. Difficulty in concentrating the mind.	.....	Father and several paternal relatives died of phthisis. Mother has nephritis and has had left hemiplegia. One sister has hystero-epilepsy and asthenopia.	R. + 1.00s L. + 1.00s	Esophoria, 16°. Right hyperphoria, 3½°.	Graduated tenotomies of both interni and of the right superior rectus.	In this case, the results have thus far been negative, in spite of patient watching and repeated eye-tests. The patient has also been treated for deflection of the nasal septum by Dr. Delavan, of New York, without relief to his head. Professor J. W. Wright, of New York, also, at my suggestion, treated the patient for an anal fissure and hemorrhoids; but no improvement of headache has followed.
28		M.	Married.	Sick-headaches. Insomnia. Mental depression. Sense of pressure in occipital region.	4 years. do. do.	Headaches are common in the maternal ancestry.	R. + 0.50s + 0.75c L. + 1.00s	Esophoria, 2°.	Given for constant wear: O. D. + 0.75c O. S. 1° prism, base out.	Patient has never reported the results of wearing his glasses. Friends of the patient state that he is now able to attend to his business in a distant city much more regularly than before.
29	27	M.	Single.	Neuralgic headaches. Intractable insomnia. Asthenopia. Indigestion. General nervousness.	Since childhood. do. do.	Father is very nervous and has severe headaches. Two brothers are also very nervous and have severe headaches.	Emmetropia.	Left hyperphoria, 2°. Esophoria, 15°.	Graduated tenotomies of right inferior rectus and of both interni.	This patient is now entirely cured of headache and his nervous dyspepsia. His asthenopia has almost entirely disappeared.
30	35	F.	Married.	Sick-headaches. Difficulty in raising the eyelids. Transient attacks of numbness of the lips and paresis of the limbs. Constant headache.	Since childhood. 3 years. do. do.	Father died of an abscess. One aunt has severe headaches.	R. + 0.50s L. + 0.50s	Left hyperphoria, 1¼° Esophoria, 12°.	Graduated tenotomies of right inferior rectus and of right internal rectus.	Patient reports her condition as one of practical restoration to health. Her headaches are rarely developed, and only after some overexertion, loss of sleep, or fatigue.
31	27	M.	Single.	Supra-orbital neuralgia (almost without cessation). Dyspepsia. Pain in right eye. Has been in very delicate health.	10 years. do. do. Since childhood.	Father suffers with his eyes. Mother and sister have neuralgia. One maternal uncle died of phthisis.	R. + 1.00s L. + 1.00s	Esophoria (totally latent) amounting to 17°.	Graduated tenotomies on both interni.	This patient has lately shown some esophoria that was not manifested for ten months after the last operation. He has been restored to health and comfort, and has passed many months without pain.
32	43	M.	Married.	Sick-headaches. Dyspepsia. Severe insomnia. Partial right hemianæsthesia. Transient diplopia.	Since childhood. 25 years. 5 years. 6 years ago. When a child.	Father had headaches. Two sisters and two cousins died of phthisis.	R. + 1.00s L. + 1.00s	Esophoria, 30° (mostly latent). Left hyperphoria, 2°.	Graduated tenotomies of both interni and of right inferior and left superior.	Headaches were improved but no effects upon the distressing insomnia were obtained. The patient left for the distant West, to live on a ranch, before his esophoria was fully corrected.
33	36	M.	Married.	Sick-headaches. Nervousness and irritability. Weak heart. Indigestion.	Since childhood.	Phthisis on maternal side. Paternal ancestry were all dyspeptics. Maternal grandfather was insane for a time. One maternal uncle was "queer," disappeared suddenly, and has never been heard from.	R. + 2.25s L. + 2.00s	Esophoria, 13°.	Given for constant wear: O. D. + 1.25s O. S. + 1.00s Graduated tenotomies of both interni.	This patient reports that he is "practically well of headaches, and cannot get along without his glasses." He has gone to Kansas City to practise medicine.
34	26	F.	Single.	Neuralgic headaches. Asthenopia. Persistent trembling in hands and arms. Rigidity of neck and "choking-spells," when attempting to speak or when excited. Severe pain in the neck. Contracture of hands and arms.	Since 10th year. do. 4 years. do. do.	Patient knew little of her ancestry.	R. + 0.75s L. + 0.75s	Esophoria, 20° (mostly latent). Left hyperphoria, 3°.	Graduated tenotomies of both interni, and of right inferior and left superior rectus. A full correction of hyperopic by glasses.	For full report, see history of this case. The patient is practically cured, but has some choreic symptoms remaining, which appear under undue excitement.

A Tabulated Record of Fifty Consecutive Cases of Headache and Neuralgia treated exclusively by the Correction of Eye-strain.—Continued.

Case.	Age.	Sex.	Condition.	Symptoms.	Duration.	Heredity.	Visual tests.		Treatment.	Remarks on Case.
							Refraction.	Muscular.		
35	28	M.	Single.	Sick-headaches. Nervousness and some tremor when excited. Partial impotence.	Since childhood. do. 5 years.	Mother has headaches. One brother and one sister have severe headaches.	R. + 0.50ˢ L. + 0.50ˢ	Esophoria, 11°.	Graduated tenotomies of both interni.	Cured of headache. The patient is much less nervous, and has nearly regained his sexual powers.
36	25	M.	Single.	Headaches. Periodical attacks of vomiting and indigestion. Slow heart's action. Cold extremities. Physical weakness. Irregular action of bowels (constipation and diarrhœa).	Since childhood. do. do. do. do. do.	Mother has headaches, and has had pulmonary hemorrhages. Father has neuralgia of the stomach. Maternal grandmother and two uncles died of phthisis.	R. + 0.50ˢ L. + 0.75ˢ	Esophoria, 20°(mostly latent).	Graduated tenotomies of both interni. Spherical glasses for reading.	This patient was a divinity student. He was sent to me from Vermont. His recovery was rapid and complete. His last communication is full of expressions of delight over his ability to pursue his studies.
37	..	F.	Single.	Headache (violent sick-headache, which during past few years became almost uninterrupted). Obstinate dyspepsia.	Since childhood. do.	Father suffered with headache and died of hemiplegia. Phthisis in maternal ancestry.	R. + 3.00ˢ L. + 3.00ˢ	Exophoria, 9°.	Given for constant wear: + 1.75ˢ Graduated tenotomies of both externi.	Patient reports that she has "not had a headache for past six months;" also that her "physical condition is better than at any time in her life."
38	52	F.	Married.	Sick-headaches (very severe and frequent). Attacks of tremor. Hyperæsthesia of entire body. Neuralgic attacks. Insomnia.	Since childhood. do. 30 years. do. do.	Father had severe headaches, and was slightly cross-eyed. Mother was a confirmed invalid. One sister has terrible headaches. One brother is a great nervous sufferer. Headaches and nervous prostration are family traits on both sides.	R. + 1.25ˢ L. + 1.25ˢ + 0.25ˢ	Esophoria, 14°(mostly latent). Right hyperphoria, 1½°.	Given for constant wear: + 1.25ˢ O. D, + 1.25ˢ = + 0.25ˢ O. S. Graduated tenotomies of both interni and of the left inferior rectus.	Headaches almost totally arrested. Insomnia cured, as is also the tremor and hyperæsthesia.
39	21	F.	Single.	Sick-headaches (very severe and constant when she uses her eyes). Asthenopia.	Since 15th year. do.	Father, mother, and sister have headaches and neuralgia, and weak eyes. Phthisis frequent among paternal ancestry.	Manifest emmetropia. Atropine not used.	Esophoria, 10°. Right hyperphoria, 2°.	Given for constant wear, 2° prism, baseout, in each eye.	This patient went nearly six months without a headache after her prisms were ordered. The parents refused atropine and operative procedure. She has had some return of headache lately.
40	46	F.	Single.	Headaches (chiefly orbital and frontal). Neuralgia in 5th nerve. Obstinate insomnia. Constipation. Palpitation of heart.	Since childhood.	Mother, maternal grandmother, one brother, and one sister had phthisis; also several paternal aunts. Father died of chronic diarrhœa.	R. + 3.50ˢ L. + 1.50ˢ Presbyopia. + 3.00ˢ	Exophoria, 6°.	Given for constant wear: + 1.50ˢ O. D, + 1.50ˢ O. S.	Results negative. The patient had one very defective eye which could not be rectified, and which made her tests very unreliable. No encouragement of marked improvement could be given her.
41	38	M.	Married.	Sick-headaches. Intense suffering from light. Tight band at temples and numbness of head. Insomnia. Irritability and physical weakness. Diplopia.	Since childhood. 2 years. do. do. do. At times.	Father died of heart disease and was very nervous. One sister has severe headaches. Most of the family have severe migraine. One paternal cousin died of phthisis.	Emmetropia.	Esophoria, 9°. Right hyperphoria, 3°.	Graduated tenotomies of both interni and of left inferior rectus.	The patient made a practical recovery. He has headache and asthenopia only at intervals, and always from excessive use of the eyes in preparing sermons, etc.
42	28	M	Single.	Frontal headache. Neuralgia. Asthenopia. Intolerance of light.	5 years. Until 1883. Since childhood. do.	Mother had headache and neuralgia and died of a tumor. One brother has neuralgia. Insanity and hypochondria common on maternal side. Maternal grandfather had cancer.	R. + 4.00ˢ L. + 4.00ˢ	Esophoria, 7°.	Given for constant wear: + 2.50ˢ = 1¾° prism, baseout, in each eye.	Patient reports that he now practises medicine with greater comfort than for many years. He has little, if any, asthenopia or headache.
43	58	M.		Sick-headaches (very violent). Asthenopia.	Since youth. do.	Phthisis common on paternal side; also rheumatism.	R. + 2.25ˢ + 1.50ˢ L. + 1.25ˢ + 0.50ˢ	Exophoria, 19°. Left hyperphoria, 4°.	Given for constant wear: O. D. + 2.25ˢ = + 1.50ˢ O. S. + 1.25ˢ = + 0.50ˢ Graduated tenotomies of both externi and right inferior rectus.	This patient's age was against him. His refractive conditions were unlike and hard to perfectly correct. He reports a very marked decrease of headache and asthenopia. He is still under my observation.
44	41	M.	Married.	Headache. Insomnia. Morbid feelings with delusions. Melancholia with suicidal tendency.	Since 20th year. 2 years. do. do.	Father died of tumor. Mother is a chronic invalid. Sister has slight hysteria. Paternal grandmother died of phthisis. One paternal uncle a suicide. One aunt was insane.	R. — 3.50ˢ — 1.00ˢ L. — 3.50ˢ — 1.00ˢ	Exophoria, 2°. Right hyperphoria, 2°.	Given for constant wear: — 3.50ˢ = 1.00ˢ O. D, — 3.50ˢ = 1.00ˢ O. S. Graduated tenotomies of right external and left inferior recti.	Complete restoration to health. No return of symptoms for past two years.
45	40	M.	Married.	Neuralgia. Sense of pressure in the head. Vertigo. Morbid fears. Insomnia.	Several years. do. do. do. do.	Two second-cousins insane.	R. + 1.00ˢ L. + 1.00ˢ	Esophoria, 10°.	Graduated tenotomies of both interni.	Patient promised to return for further observation, but has not yet done so. The last report was one of marked improvement.
46	19	F.	Single.	Headaches (severe and constant). Convulsions of the epileptic type. "Fainting attacks." Nervous prostration.	3 months. When a child. During past 6 mos. 6 months ago.	Mother is very nervous.	R. + 5.50ˢ L. + 3.00ˢ	Exophoria, 8°.	Given for constant wear: O. D. + 3.50ˢ O. S. + 1.50ˢ	Patient has worn the glasses for two years without a headache or convulsive seizure.

A Tabulated Record of Fifty Consecutive Cases of Headache and Neuralgia treated exclusively by the Correction of Eye-strain.—Continued.

Case.	Age.	Sex.	Condition.	Symptoms.	Duration.	Heredity.	Visual tests.		Treatment.	Remarks on Case.
							Refraction.	Muscular.		
47	47	M.	Married.	Sick-headaches. Watering of the eyes in cold weather. Asthenopia.	Since 16th year. 3 years. do.	Mother died of schirrus; father of prostatic trouble. Brother died of phthisis.	R. + 0.75^{s} L. + 0.50^{s}	Right hyperphoria, 1°. Exophoria, 1°.	Graduated tenotomy of right superior rectus.	Patient left for his home in California. He reports a very decided relief from headache and asthenopia.
48	33	F.	Married.	Sick-headaches. Asthenopia. Constipation.	Since 8th year. 10 years. do.	Mother, maternal grandmother, one maternal aunt, one maternal uncle, one brother, and one sister died of phthisis.	R. + 3.00^{s} L. + 3.00^{s}	Esophoria, 15°. Left hyperphoria, 1°.	Given for constant wear: + 2.00^{s}	Patient has been benefited by glasses ordered. Her husband refused consent to an operation for the muscular maladjustment.
49	32	M.	Single.	Headaches.	Since childhood.	Father has severe headaches. Mother died of puerperal fever. One brother has headaches.	R. − 0.50^{c} L. − 0.25^{s}	Esophoria, 8°. Left hyperphoria.	Given for constant wear: O.D. 1° prism, base up. O. S. 3° prism, base out.	No report has ever been received from this patient. He lives in the West and has not returned for further treatment.
50	40	F.	Married.	Neuralgic headaches (causing coma of 24 hours' duration).	Since 14th year.	Father died of paralysis. Mother had "suffocation spells." One sister is very nervous. Dyspepsia is a family trait.	R. − 2.50^{s} + 0.75^{c} L. − 2.50^{s} + 1.50^{c}	Left hyperphoria, 6°.	Given for constant wear: − 2.50^{s} = + 0.75^{c} O. D, − 2.50 = + 1.50^{c} O. S. Graduated tenotomies of left superior and right inferior recti.	Total cessation of headache for a long period of time. Occasional headaches (according to last report) after severe exertion or excitement.

I can point to case after case in my professional experience, since my own recovery, where the cause of neuralgic attacks, excruciating headache, vomiting, extreme nervousness, and many other symptoms (not apparently connected with eye-defect) would have remained unrecognized if atropine had not been employed.

There is a rule given by most oculists, viz., to give to a hyperopic patient the strongest convex glass[1] with which he can comfortably read the normal test-type (XX) at a distance of twenty feet. It is impossible in many cases to decide this fact without atropine or an ophthalmoscope. The former method is the best one, because the accommodation of the oculist, as well as that of the patient, has to be excluded in the latter, and it has the advantage that it can be employed by the general practitioner as well as by the specialist.

It is advisable to caution the patient, after using this drug, that he may possibly suffer from the sunlight, and that colored glasses will relieve him of this annoyance. It is also best to tell him that his vision may become very blurred for distant objects in case he is far-sighted; and that, in any case, he will be unable to read or to write by the aid of vision without glasses for several days.

I have known hyperopic patients to become greatly alarmed at the rapid loss of vision which has followed the use of atropine; all of which could easily have been avoided had they been prepared for it by timely words of explanation. It is always well to explain to far-sighted subjects the difference between "manifest" and "latent" hyperopia, and to make them intelligent as regards the effect of atropine upon the "focussing" muscle before you administer it. If they are forced by their business to use their eyes for near-work while under the influence of atropine, a pair of cheap glasses may be given them for temporary use while under its influence.

I cannot impress too strongly upon my readers the necessity of using atropine upon a patient (if young) for diagnostic purposes when an error of refraction or of accommodation is suspected. Personally, I do not regard an examination as complete without it. It solves the question of the presence of "latent" hyperopia—a very common defect, and possibly a very serious one (from the stand-point of the neurologist) if allowed to go unrecognized. It reveals the existence of a previous ciliary spasm. It often arrests headache as if by a magic touch, and solves the nervous origin of many other similar symptoms.

Patients who boast of their acuteness of vision, and who apparently justify their statement by reading test-type at a distance without the aid of glasses, are often astonished, and sometimes alarmed, at the immediate loss of this power which is brought about by the use of atropine. This surprise is heightened when (by the use of proper lenses) their power of vision for distance is immediately restored, and they become conscious for the first time of the muscular effort which they have been compelled in the past to exert in order to see without them. I shall never forget, personally, the sensation which I experienced of "seeing without effort" when latent hyperopia was discovered in my own eye, and corrected by glasses.

These experiences are well-known facts among oculists, but to the profession at large they often occasion as much of a surprise as to the patient.

I usually employ a solution of four grains of sulphate of atropine to an ounce of distilled water. This can be kept constantly in your office in a phial with a rubber-top dropper substituted in place of a cork A drop or two in each eye will suffice, in most subjects, to dilate the pupil widely, and to paralyze the power of accommodation of vision for near objects in about three hours. In occasional instances it became necessary to keep the patient under its influence for several days, but this is not the rule.

In this contribution it is my purpose to present, as a supplement to others previously published by myself, a report of fifty consecutive cases of typical headache and neuralgia, taken from my private case-book, as confirmatory of the views that are here advocated.

Space will not allow of the full records of all of these cases. I have concluded, therefore, to tabulate the main points of each case,[1] and to give histories of those only that presented some particular difficulties either in diagnosis or treatment. These will be numbered so as to correspond to the table. In such a tabulated record it is impossible to show many fluctuations observed in the muscular tests during treatment.[2]

[1] The advisability of a full correction by glasses, of existing hyperopia can only be decided after the condition of the patient, his age, his susceptibility to reflex irritation from eye-strain, etc., have been carefully considered. It is not usually advisable to force a young subject to wear a glass which fully corrects the latent hyperopia.

[1] The terms used in this table are those first suggested by Dr. G. T. Stevens, of New York (New York Medical Journal, December 4, 1886):

"*Esophoria*" signifies a deviating tendency of the eyes inward; "*exophoria*," a similar tendency outward; "*hyperphoria*," a similar tendency of either eye upward.

In the table appended to this article I have noted the refraction only as observed when the eyes were under atropine.

[2] Every patient examined for defective equilibrium in the eye-muscles instinctively strives (not by mere volition) to get binocular vision

CASE III.—This case is one of special interest. Both the patient and her sister had been delicate for many years. The patient had never menstruated; had been addicted to "fainting-spells" which occurred frequently, and at the most inopportune times, so that she would fall unconscious in the street, etc.; had suffered from melancholia, so that once she attempted suicide; had been a victim to nervous dyspepsia; and had suffered more or less from asthenopia.

Her family history was a bad one, showing a marked heredity to nervous derangements. The mother had the same "fainting-spells;" the maternal uncles all died of diabetes; one cousin of the patient has epilepsy; and two other cases of epilepsy existed in her paternal ancestry.

The eye-tests showed unequal refraction in the eyes; the right eye showed a decided tendency to assume a higher plane than the left, although she could fuse her visual images, even with a red glass before either eye.

As she was unable to desist, for a time, from an occupation demanding use of the eyes at the near point, the manifest hyperphoria was corrected (within one degree) by a prism. The effect of the prism has thus far been very beneficial. Later on, it is my intention to perform a graduated tenotomy for the purpose of bringing the eyes to a proper adjustment.

That this defect in the vertical movements of the eyes is a congenital one, I have had an opportunity of quite positively demonstrating by similar examinations made upon others of her immediate family.

The so-called "fainting-spells," to which this patient was subject, are probably closely allied to epilepsy, a disease to which she is liable by heredity. It is not common for faintness to prostrate people suddenly while crossing a street (without apparent cause or warning), and to be associated with a total loss of consciousness for quite a prolonged interval.

CASE IV.—This patient presents a peculiar heredity to nervous derangements. Insanity, epilepsy, and headaches have been developed in the ancestral lines. The patient has had attacks of marked "petit-mal," in which consciousness would be suddenly lost for intervals of from five to fifteen minutes. His eyes began to cause him distress about two years before I saw him.

His mental faculties had at times been rendered peculiarly sluggish, so that the patient felt unable to handle complex business problems.

CASE V.—This case presents a peculiar instance of marked relief from a prostatic neuralgia (which bids fair to entirely disappear without local treatment) after the cessation of "eye-strain." Headache and sleeplessness also existed as sources of great distress.

I have previously reported a remarkable case of this type of neuralgia (*New York Medical Journal*, January 7, 1888), which bears upon the correction of an eye-defect to such an extent that I quote it in full, as follows:

"*Melancholia, Morbid Impulses, Cerebral Confusion and Distress, and an Intractable Prostatic Neuralgia.*—Male, aged twenty-three, unmarried.

"Family History: The mother of the patient suffers from neuralgia and headache. The paternal grandfather had paralysis. The paternal grandmother was 'extremely delicate.' One brother suffers from headaches. Another brother is very excitable and of a highly nervous temperament. No case of consumption has ever occurred in any branch of the family.

"Eye-defects: Hyperopia (latent) of 2.50 D. Esophoria (manifest) 4°; subsequently 12° were elicited prior to any operative procedure.

"This patient had been under medical care for many months for a prostatic neuralgia, and had derived no benefit from local or general treatment. He developed melancholia, and would frequently retrace his steps for several blocks, during a stroll, in order to touch some object which he felt he should have touched when he passed it. The use of his eyes intensified his mental symptoms markedly. He also suffered from morbid fears. He had never had venereal disease. After partial tenotomies were performed upon his interni, and his hypermetropia was corrected by + 1.50 spherical glasses, his recovery was very rapid and complete. He has had no abnormal mental symptoms or neuralgia of his prostate since the first operation (now nearly two years). His father, one brother, and a sister have since been examined by me, and all had very marked eye-defect."

I have, at the present time, a third case under my care which I think belongs to the same class of reflex neuralgias.

In every one of these three cases the relationship between eye-strain and the prostatic neuralgia had never been suggested to the patient by any of their numerous medical advisers or by their eye-symptoms. All had tried local treatment, directed to the prostate gland, without satisfactory results, under skilful and experienced hands.

CASES VI and VII.—These were typical cases of severe paroxysmal pain, in which very gratifying results were quickly obtained by a graduated tenotomy of one muscle. Both had tried drugs without benefit.

CASE VIII.—This patient (the wife of a prominent divine) was sent to me from a distant city as an "incurable case of sick-headache." The attacks had recurred so frequently and with such severity as to practically unfit the patient for many years for any social or household duties. All medicinal treatment had proved of no avail. No trouble had ever been experienced with the eyes, as far as the patient could recall.

Under atropine an astigmatism (+ 1.00°) was discovered and corrected by cylindrical glasses. She also manifested within a week nearly 6° of right hyperphoria, and an esophoria which fluctuated from 2° to 8°. Prisms of 5° (in total) for her hyperphoria were worn by her over her cylinders for more than three weeks, during which time her customary headaches failed to appear, and her apparent esophoria was favorably modified.

The vertical deflection was then corrected by a graduated tenotomy of the left inferior rectus.

A report received to-day from the son of this patient states that "mother is almost entirely free from pain and has had no attack of sick-headache for many weeks." The physical condition of this patient has improved to such an extent as to render her capable of daily feats of exertion that had heretofore been deemed impossible.

CASE IX.—This lady was sent to me by an oculist of prominence in the West, because he could not interpret to his satisfaction certain points of apparent conflict in the tests relating to muscular equilibrium in the orbits, nor could he cure her severe asthenopia and intractable neuralgia by any form of glass.

On the first examination any attempts to measure the sursumduction, adduction, or abduction of the eyes caused the most extreme faintness and nausea, so much so that they had to be desisted from at that time. The patient disclosed, however, after some days of careful observation, a high degree of hyperphoria, with esophoria of 14° (causing homonymous diplopia with a red glass).

The correction of her astigmatism by glasses, and the relief of the abnormal muscular tension in the orbits by graduated tenotomies on three muscles has greatly improved her condition; but I am inclined to doubt if her deviating tendencies in the orbit have yet been completely rectified.

Her neuralgia and headaches have been lessened in frequency and severity at least one-half, and her asthenopia was decidedly diminished when she last wrote me.

---

under the nearest approach to physiological conditions of which he is capable.

We are forced to admit, therefore, that what we detect in any patient and record as an error is in reality only what the patient cannot conceal, not necessarily all the defect in the muscular adjustment that actually exists.

Because a patient can momentarily perform a feat of eye-balance which approaches the normal state, by the aid of his reserve power, it is by no means proved that the eyes are habitually in equilibrium.

Unfortunately she is forced to use her eyes constantly at the near point.

CASE X.—This patient was sent to me from a distance by her physician for relief from terrible sick-headaches that occurred once or twice each week. She also was unable to use her eyes for reading, sewing, or any prolonged effort without a severe headache occurring within twenty-four hours. She had been confined in bed for months, at one time, from an attack of "nervous prostration."

She disclosed a high degree of hyperphoria and esophoria. These abnormal conditions seem at the present time to have been satisfactorily rectified by three graduated tenotomies.

In one of her last communications to me she says: "To say that I feel better would be expressing it in very mild language. I feel perfectly lovely, and can stand almost anything."

CASE XI.—In the ocular conditions of this patient a most complex anomaly of adjustment of the eye-muscles was encountered. The heredity of the patient was a particularly bad one. Phthisis and epilepsy had developed in both the maternal and paternal ancestral lines, and one brother had developed epilepsy (with attacks closely bordering upon insanity) before the age of ten years.

Repeated graduated tenotomies have thus far been performed upon the eye-muscles with happy results both as to the expression of the eyes and the frequency of headache; but the results are not yet what I believe they will be, when the conditions encountered are perfectly rectified. Such conditions as were observed in this case require time, patient observation, and extreme care in treatment.

CASES XII., XIII., and XIV.—These were simple cases to diagnose and combat. Neither of them have yet passed from under my observation. All were treated by me by graduated tenotomies of the eye-muscles for some manifest anomaly. The improvement noted in all has been gratifying to the patient as well as to myself.

CASE XV.—This young lady was sent to me by a prominent New York surgeon, under whose care she had been, and at whose advice a plaster-jacket had been worn continuously for a year with the hope of controlling a constant pain in the spine between the shoulders and in the lumbar region. She had also been under the care of one of the leading New York gynecologists, who had helped her somewhat she thought, but had not relieved her head or spine. Her physical condition was one of extreme and progressive debility. Over two weeks elapsed before she could endure a carriage-ride to my office, after a letter of introduction had been given her, although she was living but a short distance from it, and the weather was favorable. She had, when I first saw her, constant headache and spinal pain; was unable to read, write, or sew, and could sleep only a small part of each night. The condition of her eyes proved to be a very complex and difficult problem to solve and rectify. She disclosed, after patient observation, a high degree of hyperphoria (almost totally latent) and also a homonymous diplopia (when a red glass was placed before either eye). Repeated graduated-tenotomies were performed upon the eye-muscles within a period of three months, when she returned to her home in a Southern State. Before she left New York she was walking about three miles each day; had experienced a great relief from her headache and spinal pain, and was better than she had been for many years. In one of her written communications lately received she says: "I am sleeping better and the pain between my shoulders is decidedly better. I have less pain in the back of my head. I drive, walk, entertain company, and go to church every pleasant day, so I know I must have gained in strength even since you last saw me." This case very closely resembles one reported by me in the *New York Medical Journal* January, 7 and 14, 1888, which will bear repetition here. My record of this case is as follows:

"*Cerebral Neurasthenia, Constant Pain in the Head of Five Years' Duration, Asthenopia*, etc.—Female, unmarried, aged twenty-one years.

"Family History: Maternal aunt and five paternal relatives died of phthisis; two cousins had chronic chorea.

"Eye-defects: Patient had hyperopia (latent) of 1.25 D., and exophoria (manifest) of 2°. A latent hyperphoria of 2° was subsequently discovered.

"This young lady was brought into my office by two assistants, who were obliged to carry her from the carriage. For several years she had been carried daily from her room to the library of her father's house, and, after reclining in a chair for a few hours, she would again be carried to her bedroom. She could manage with difficulty to walk slowly across a room. She had not been able to write, read, sew, or see her most intimate friends for five years on account of a constant pain in her head, which was rendered intolerable by any use of the eyes or excitement. Her symptoms began while at boarding-school, from which she was removed to her home in a recumbent posture and by easy stages.

"I used static electricity upon this patient for some weeks with a slight improvement in her power of walking, but no relief to her head. I then persuaded her to consent to a relief (by partial tenotomies) of her abnormal eye-tension. Tenotomies were then performed upon her left superior rectus and both externi within the space of two weeks. From that date her improvement was very rapid. She was sent home a few weeks later practically cured."

A letter from her physician, lately received by me, says:

"Your patient is the wonder of this region. She rivals the 'Jersey Lily' in her feats of walking."

Before this patient was sent home she ascended and descended five flights of stairs daily, and averaged over a mile's walk each day without a companion to assist her.

I would add to this record that this patient lately called at my office and informed me that she was studying physical culture, with a view of teaching it.

CASE XVI.—This case is one of the most puzzling problems that I have yet encountered. The patient is a young lady who has suffered from a constant pain over the eyes that nothing would relieve. She had been under the best medical care, and had consulted a very prominent oculist, who advised "a weak reading-glass." Her pain still remained unabated. For a long time after I had the opportunity of testing her eyes she failed to disclose a left hyperphoria, which her expression justified me in suspecting. Prisms were worn by the patient for this defect as fast as she revealed it (always keeping about one degree behind what the patient disclosed), until a total of nearly eight degrees of hyperphoria was revealed by the patient. Two graduated tenotomies were performed to correct this deflection (the left superior and the right inferior muscles being button-holed). Both muscles were found to be enormously hypertrophied. The tendons were as thick as heavy buckskin. Subsequently both of the externi were operated on for an exophoria that had always manifested itself. The results thus far have been that the patient is greatly relieved from her headache, but is not absolutely cured. Her muscular balances seem to be nearly perfect.

CASE XXI.—This case has not progressed as well as I at first anticipated it would. The patient's eye-tests at the first interview led me to hope for marked and immediate benefit, but the results thus far are not as rapid as I expected. The patient was obliged to return to her home in the western part of this State, and I placed her under the care of an oculist who is quite well versed in the treatment of mal-adjustments of the eye-muscles. Before she left New York I had reason to suspect the existence of a latent hyperphoria. It is probable that further observation and time will reveal some vertical tension in the orbit.

CASE XXIII.—This girl weighed, when I first saw her, but ninety-two pounds, although five feet five inches in height. She was in a nervous condition that justified alarm, as morbid fears and emotional disturbances were becoming very pronounced. Her headaches were peculiarly distressing and very frequent. She had been under the care of several prominent physicians, and one oculist of note. A weak cylinder had been prescribed for the right eye, to be used while reading or sewing. A latent hyperphoria of 4° and an exophoria of 5° were corrected by three graduated tenotomies. She is now better in health than for many years past, and has gained some ten pounds in weight.

CASE XXIV.—This patient is a physician. Since childhood he has had a peculiarly "weak stomach," and neuralgic headaches of a severe type. Without a known exception his maternal ancestry for several generations have been similarly affected. His mother and one brother died of brain disease. Two sisters are victims to excruciating headaches. His father and paternal ancestry suffered more or less from sick-headaches. Within the past fifteen years the patient has had frequent attacks of vertigo, and more or less "confusion of thought" at times. Insomnia has also become almost a habit. The beneficial results of eye-treatment have been very marked in this case. He had esophoria of a high degree, and some left hyperphoria, to relieve which I performed three graduated tenotomies. The last reports from this patient would indicate that he is in better health than at any previous period. He expresses himself as particularly grateful for the improvement in his headaches, digestion, and ability to sleep. He can now read, travel in the cars, and do gynecological work without distress in his head; all of which used to be particularly difficult for him to attend to without entailed suffering.

CASE XXV.—This is particularly of interest from the fact that the patient had been afflicted for six years with very frequent paroxysms of neuralgia over the eyes, of an excruciating type, accompanied by vomiting, that were apparently due to diabetes. Dr. George T. Elliott, of New York, examined the urine several times while the case was under treatment, and noted a steady decrease in the percentage of sugar, without the aid of drugs or restricted diet—from three per cent. to one-third of one per cent. The patient showed a high degree of left hyperphoria and esophoria. Graduated tenotomies were performed for the relief of the hyperphoria only, and for quite a long time all the neuralgic paroxysms ceased, and the improvement in the patient's condition was very marked. Unfortunately, the patient has thus far failed to allow me to complete the restoration of the other deviating tendency. I have received a letter from him lately in which he states that he has discontinued glasses, and that his headaches have returned. I have advised him to return to New York and complete the line of treatment commenced. His urine has been repeatedly tested by his physician, and he has found no trace of sugar at any time.

CASE XXVII.—All efforts made thus far to relieve this patient of headaches have proven of no avail. No evidence of any organic disease has been detected by any of the physicians who have had him under their care. The heredity of the patient was bad, and justified me in hoping for better results. Phthisis was common in the paternal line. The mother had hemiplegia. A sister (now under my care) has very severe attacks of catalepsy and hystero-epilepsy. Twice in her life she has been supposed to be dead, laid out for burial, and the clothing prepared. This case was under the care of Dr. C. L. Dana, of New York, for quite a long time. He obtained negative results from electrical treatment and drugs. At my suggestion (when the apparent eye-defects had been quite satisfactorily overcome without any decided benefits) this patient placed himself under the care of Dr. J. W. Wright, of this city, for the relief of an anal fissure and hemorrhoids. No marked change in the headaches followed the removal of this source of reflex irritation. As he also had a very marked deflection of the nasal septum, I advised him then to have that corrected. This step was undertaken, with admirable success, by Dr. D. Bryson Delavan, of New York, who removed quite a large piece of the septum. Thus far all these steps have proved of no material benefit as regards the headache, of which the patient still complains. I encountered a case exactly similar to this, some two years ago, which was sent to me from San Francisco. In both cases little material benefit was obtained. It is still possible that some latent cause for eye-strain may be detected by further observation.

CASE XXIX.—This patient had been under constant medical supervision for years. Had made a trip for several months on the ocean, to fit him for work; but had collapsed again as soon as he began his eye-work in the office. Riding for a short time in a railway car (if he read or looked out of the window) would give him indescribable distress in his head, and compel him to go to bed. His family history shows the existence of phthisis, extreme neurasthenia, and severe headaches. A tendency toward melancholia in his ancestral lines has manifested itself in several instances. His brother has always suffered with headaches, and has been "weak-minded," so that he was unable to fill clerical positions with satisfaction to his employers for any length of time. Correction of a hyperphoria and a very high degree of esophoria by graduated tenotomies has effected in this patient a complete restoration to health.

CASE XXX.—This lady was sent to me by her physician because "he could find nothing to relieve her." Her headaches, although extremely violent at times, never entirely subsided. Transient attacks of numbness of the face, lips, and limbs would occur at intervals. She showed both hyperphoria and esophoria. These were corrected by graduated tenotomies. Some eleven months have now elapsed since the operation. Her headaches rarely occur, her physical strength has improved wonderfully, and she regards herself as practically cured.

CASE XXXI.—This patient had been a source of anxiety to his parents from childhood on account of delicate health and nervous debility. Since manhood, he had sought constantly for relief. "Nervous dyspepsia" had existed since early boyhood. Since the seventeenth year, supraorbital neuralgia has proved a source of almost constant distress. For over six months he was lately under the care of a prominent oculist, who ordered different reading-glasses from time to time, that failed to afford relief. He was then treated for nasal occlusion by chromic acid applications, but no benefit was experienced. He had, at times, been under the medicinal treatment of many of the leading physicians, but had obtained no permanent relief from drugs, and had become very despondent in consequence. His mother and sister have neuralgia; the latter, of a very severe and intractable form. His father is very nervous, and suffered from asthenopia until I corrected his refractive errors. In a letter lately received by me from the patient, he says: "Our benefactors are seldom remembered until a punching is received. I have been feeling so well that I've not thought of how I got there, nor the cost, until your bill came."

CASE XXXII.—This patient was a doctor. His hypermetropia was totally latent, and was disclosed only after the use of atropine. The correction of his muscular and refractive anomalies caused a most favorable change.

CASE XXXIII.—This case is well worthy of record. The patient was a poor factory girl that was sent to me by a medical friend in Massachusetts, to see if anything could be done for her, as no one who had seen her could make a diagnosis. Her appearance was one of remarkable deformity. Her chin seemed to be held firmly in the region of the fourth button of her dress. Both upper limbs were contractured in the state of semiflexion at elbows, wrists, and fingers, and trembled excessively when she tried to use them. They could not be extended, nor could the patient make much use of the hands. She had been

obliged to give up work on that account. When she talked, her face became painfully drawn and distorted. The mouth would especially be drawn downward. Under the least excitement she would be seized with what she called "choking spells." The throat muscles would contract and interfere seriously with respiration. She had constant headache—chiefly in the forehead and occiput—and a persistent pain in the neck. No painful points existed; nor did pressure, movement, or other tests reveal the existence of organic disease of the spinal cord. Sensibility to touch, pain, and temperature was normal. Motility was unimpaired. The muscular sense was perfect. No inco-ordination existed. Several photographs of this patient were taken at my request, but they failed to give an idea of the frightful contortions of the face and upper limbs that existed when the patient was unduly excited. I considered the case as one of aggravated chorea, complicated by headache and asthenopia. An examination of the eyes showed a manifest hypermetropia (+ 0.75 D.) which remained unchanged under atropine. She also showed a slight esophoria (which under prisms became a homonymous diplopia) and a left hyperphoria of 3°. These muscular anomalies were satisfactorily relieved by several graduated tenotomies, and applications of static sparks were made daily for about two months. The patient has now regained the use of both hands, carries her head erect, has no headaches, and little spinal pain, and for a while returned to work. The effect of hard labor brought back her "choking spells;" hence she was advised to take a year of absolute rest. She now has some asthenopia remaining, and an occasional headache. Her facial contortions persist to a slight extent when she is unduly excited. I suspect that some latent hyperphoria exists still, and that further operative work on the eye-muscles will be demanded before the patient recovers completely.

Case XXXVI.—This case illustrates the dependence of neurasthenia upon eye-strain. The symptoms which coexisted with headache entirely disappeared when the cause of excessive nervous expenditure was removed. A more pitiable nervous wreck than this patient was when sent to me is seldom encountered.

Case XXXVII.—This was a simple case of "eye-strain," due to a refractive and muscular error combined. The restoration to health seems to be complete. The headaches had become practically uninterrupted, and unfitted the patient for any occupation.

Case XXXVIII.—This case is one of peculiar interest because of the life-long duration of the symptoms and the various steps which had been taken to get relief. The patient was the wife of a physician, who had been obliged to abandon a lucrative practice in Chicago on account of his wife's health. She had been delicate from childhood, and eventually succumbed to constant headache, neuralgic paroxysms, failure of the digestive functions, and insomnia. She also developed tremor, hyperæsthesia of the entire body, emotional disturbances, and other symptoms of "nervous prostration." Her womb was supposed to be at fault, and all her other symptoms were deemed as echoes from pelvic disturbances. For fifteen years she had been under the best medical advice (chiefly gynecological) in the various cities in which they had at times taken up their residence. The heredity was a bad one. Almost all of the ancestors and relatives (male and female), on both sides, had given evidence of nervous troubles. The menopause had been confidently waited for as the millennium in which the supposed ovarian disturbance would cease; but the hope had proved a delusive one, as no improvement seemed to come. There had never been, until after the menopause, any trouble with the eyes, of which the patient was conscious, in spite of the fact that the cause of her nervous disturbances had without doubt been chiefly ocular throughout her life of suffering. She had reached a point, before I saw her, where seclusion from the society of friends and confinement to her own room had become a necessity. The headaches were intolerable; the use of the eyes a source of discomfort; and the physical weakness extreme. When I first saw her she was brought to my office in a carriage. Within three weeks two graduated tenotomies had been performed upon her eye-muscles. She attended a place of amusement soon after the first operation, which gave her great relief. In less than two months she undertook the care of a home of her own in Brooklyn, and visited me daily at my office for some time. She has had but little headache since the operative treatment upon her eye-muscles was begun. She still suffers, however, from acute digestive disturbances at times, which retard her recovery. At the last examination I discovered some hyperphoria which had not been relieved. This factor may be an active one in causing her gastric derangement.

Case XXXIX.—Although in this case a complete cessation of headaches for six months followed the use of prismatic glasses, the parents refused to allow the use of atropine and a radical correction of the hyperphoria and esophoria. As the patient lives at a distance from New York I have no record of her present muscular tests.

Case XL.—This patient had one eye that was too defective to be of much use. Her tests were very unsatisfactory in consequence, and little encouragement was given her. Her ocular conditions were unquestionably a very important factor in her nervous debility.

Case XLI.—This patient was a divine, and a victim to chronic sick headache, asthenopia, insomnia, and general neurasthenia. He had been obliged to desist from pastoral work in consequence of his many sufferings. At the last interview he told me that he had recovered so rapidly that he had resumed pastoral work, and now suffered but little from his old symptoms. Too close application in his study tends to cause him a slight return of distress in his head and eyes. He no longer has any double vision.

Case XLIII.—This case was a long and tedious one, and the results are, perhaps, all I am justified in expecting. I had to combat a high degree of astigmatism for the right eye, unequal refraction in both eyes, crossed diplopia (transient), and left hyperphoria of a very high degree (mostly latent). In spite of the difficulties of the case, and the amount of operative work done upon his eyes, this patient is one of my warmest and most enthusiastic advocates. He certainly has been greatly relieved of most excruciating attacks of headache, which were becoming almost incessant. His asthenopia is also greatly improved. He is still under observation with a hope of greater benefits.

Case XLIV.—This case was one of unusual interest to me. The patient had succumbed to headache, insomnia, etc., and had had an attack of the so-called "nervous prostration," which compelled him to abandon all business pursuits and take a trip to Europe, which he could ill afford. This trip gave no permanent benefit, and melancholia with suicidal tendencies developed after his return. No medicinal treatment yielded any results. He was then referred to me by his brother (a physician of prominence in this city). Graduated tenotomies were performed for esophoria and hyperphoria. The effect was immediate and startling to his family. He completely regained his health, strength, and mental vigor within six weeks. Over two years have elapsed without any signs of return of his old symptoms. Moreover, he has passed through a serious financial disaster with a buoyancy that surprised himself and others.

Case XLVI.—This case illustrates in a remarkable way a high degree of latent hypermetropia. Spherical glasses in this case have entirely arrested the headaches and convulsive attacks (to which the patient was subject) for two years.

Case XLVII.—This patient was a physician. He reports that very marked improvement, not only in his headaches and asthenopia, but in his general health, has followed the relief of his eye-strain.

CASE L.—The final case reported is one of the most remarkable that I have ever encountered. The patient was brought to my office from her home in Virginia by her sister, who wrote to me as follows, before her arrival:

"My sister at one time thought her headaches came from her teeth; and she had twenty-six drawn. This may give you some idea how tremendously in earnest she is about being cured."

When a child, headaches would appear after a transient attack of blindness. They increased in frequency so that, after marriage, two a week often occurred (each lasting twenty-four hours and followed by two days of confinement in bed from exhaustion). When pregnant, she had several "falling fits" daily, and remained totally unconscious for some time. She seldom passed a week without being unconscious or semi-comatose from pain. The slightest exertion caused "palpitation of the heart" to such an extent as to cause a fear of approaching death. A correction of the hyperphoria by graduated tenotomies caused almost complete restoration of health.

The patient reports that during the past six months "she has had but three headaches—two light and one severe—the latter being caused by intense emotional excitement." I learn from her also that she can bear fatigue without any of the bad symptoms that used to inevitably follow. She was only under my observation a very short time; hence I suspect that the hyperphoria may yet be imperfectly corrected. Before she left New York she journeyed some fifteen miles daily to visit my office, and experienced no distress after the effort.

156 MADISON AVENUE.

ACUTE ŒDEMATOUS UVULITIS, WITH CASE.[1]

BY J. DUDLEY MORGAN, A.B., M.D.,

ASSISTANT SURGEON TO THE THROAT AND CHEST DEPARTMENT, CENTRAL DISPENSARY, WASHINGTON, D. C.

MOST authors, in writing of acute œdema uvulæ, or acute uvulitis, affirm or infer that the œdema is caused by or associated with cold, and that the pharynx and tonsils will show a sympathy of congestion somewhat proportionate to that acutely present within the uvula.

Mackenzie[2] says: "Some cases where the pharynx is inflamed the violence of the morbid action appears to be expended on the uvula." Sajous[3] speaks only of relaxed throat and uvula, which may be caused by chronic catarrhal inflammation; and Heath,[4] of œdematous uvula due to inflammation, and commonly found in any acute inflammation of the throat. Ingals,[5] in his lectures on the throat, does not mention the subject. Browne,[6] of London, in his recent edition, writes to the point. He says: "The uvula becomes suddenly red, swollen, and infiltrated, with comparatively little hyperæmia of the neighboring parts." Cohen[7] notes that œdema uvulæ sometimes occurs during the progress of acute or chronic sore throat, and the organ may acquire the size of a large bean, or even that of a plum, and will provoke spasms of impending asphyxia.

The case in question seems to be a unique one, and a striking exception to the doctrine laid down by most of the authors consulted. Mr. M——, a patent attorney, aged forty, was, on the morning of April 14th, in perfect health and had never been treated for throat trouble. In the afternoon, which was clear and balmy, he experienced no symptoms of cold or catching cold. Later in the same evening his throat began gradually and steadily to fill up, and within four or five hours spams of suffocation attacked him. The patient described it as though his tonsils had fallen and were movable in the throat. He could not swallow anything solid, and liquids only with great difficulty. He had no fever, his tongue was moderately coated, and his daily regulations of life were and had been good. He had eaten a rather heavy dinner about eight o'clock, and had smoked and drank, but not to excess. It was not until near twelve at night that his throat commenced to feel uncomfortable, although for several hours previous he had experienced frequent and annoying eructations. Early the next morning he came to my office, asking to be seen immediately.

Inspection by aid of strong reflected light revealed a limited, but intense, palatine congestion, and an enormous œdematous uvula. The tonsils, palatine folds, and pharynx were not hyperæmic, and the patient complained of no pain on pressure externally against the tonsils, nor were they at all prominent to the touch. The uvula was fully the size of the thumb in thickness, and on inspiration and expiration would flap back and forth, sometimes lying as a great pendulous mass on the tongue, and then, on forcible inspiration, dropping deep in the fauces, setting up a succession of paroxysmal coughs.

With the aid of Ingals' dressing-forceps, I grasped the swollen uvula in expiration at its most pendulous portion, and made a number of stabs with the bistoury; but finding only little bleeding I used a large needle, held firmly within the needle-holder, thrusting the point many times deep into the tissues. The oozing of blood and serum was so little, and the swelling had diminished to such a slight degree that, after waiting some fifteen or twenty minutes more, I determined to try the effect of a strong solution of cocaine. I therefore painted the whole uvula with a fifteen per cent. solution, and made another application within ten minutes. The engorgement now commenced immediately to disappear, and was reduced considerably before the patient left the office, he expressing himself as feeling freer and more comfortable about the throat. I ordered a dose of Rochelle salts, a gargle of tannin, aconite, and rose-water; to use no warm drinks, and to take little or no food, and that of a liquid character.

The same day, six hours after, the patient returned to the office, expressed himself better, and on inspection I found the swelling had subsided fully one-half. Reapplied the solution of cocaine and continued liquid diet. Next day the uvula was almost normal in size; throat perfectly comfortable; patient discharged, cured.

I was led to the trial, in this affection, of cocaine, knowing full well its power of readily reducing the turgescent mucous membrane in acute affections of the nasal passages. Its use in acute œdematous uvulitis may have been specially recommended; if so, I have failed to find mention among the number of works I have consulted. Laffont,[1] of Paris, speaks of the local effect of cocaine in increasing the functional activity of the sympathetic nervous system, causing contraction of non-striated muscular fibres. Bosworth[2] claims that cocaine produces rigid contraction of unstriped muscular fibres, and that, topically applied, it will so constringe the blood-vessels of an acutely inflamed mucous membrane as to arrest the disease. Wood's[3] experience is that in some acute mucous inflammations the primary bleaching is permanent.

To explain this rapid and localized œdema, and equally rapid and permanent disappearance, I believe we must look to the vaso-motors as being greatly at fault. The uvula is in direct communication with the stomach, through the sympathetic system. Flint[4] says there can be no doubt that the sympathetic branches contain filaments capable of modifying the calibre of blood-vessels. We can trace the nervous origin by many routes; one among

them is through the descending palatine branches into Meckel's ganglion, thence to the sympathetic root, on to the carotid and gastric plexus. But the most direct and easily explainable route is by the afferent branches of the pneumogastric, joining with the filaments to the superior cervical ganglion, branches from which ganglion, forming a plexus on the external carotid artery, are distributed to the ramifications of this artery.

I regard this case as an illustration of a phenomenon acting reflexly through the sympathetic system, localized in its manifestation and operating from the stomach—a function not foreign to the sympathetic when we remember the important influence which the sympathetic always plays upon nutrition, calorification, and secretion.

The rapid course which this disease ran shows, first, how the stomach may reflexly and acutely act upon the upper air-passages; second, that by giving rest to the stomach and causing a depletion, local and general, we effected a termination of this disease as hastily as it was acutely manifested.

NEPHROPHTHISIS, WITH SWELLING OF THE URETER ON ONE SIDE.

A few Remarks on Palpation of the Ureters in the Female.

By J. SCHMITT, M.D.,

GYNECOLOGIST TO THE G-RMAN DISPENSARY AND POLYCLINIC, NEW YORK.

Diseases of the bladder, the ureters, and the kidneys, in spite of the improved method of examining, not seldom lead the practitioner into doubt in deciding the seat of the lesion. Concerning the subjective symptoms, we cannot admit of any such as characteristic of pathological changes of a certain organ. Particularly, frequent and painful micturition, formerly considered as indicative of a diseased bladder, is just as frequently met with in cases of pyelitis and nephritis. Even the results derived from physical examination are not so devoid of objection as one might desire. This especially applies to the microscopical researches. While some authors claim it impossible to base a diagnosis upon the epithelia found in the urine, others feel justified to diagnosticate diseases of the bladder, the pelvis, and the kidney from the mere appearance of the different epithelia in the urine. In one point they seem to be not at variance—aside from the significance of the epithelium of the bladder—namely, with reference to the tile-shaped, caudated epithelia of the pelvis. But I cannot conceive why special stress is laid on the tile-shaped arrangement, inasmuch as I would not hesitate in pronouncing all the coherent epithelia equally arranged like tiles.

The shape and the relative size of the different epithelia is certainly of a greater value in trying to come to a conclusion.

The facilities of making a diagnosis as to disorders of the urinary organs are greater in the female. The catheterization, or temporary occlusion of the ureter, is applicable. Besides, after the dilatation of the urethra, the condition of the lining surface of the bladder can be directly made out with the finger, and many details can be disclosed by vaginal exploration. We are even able to palpate the ureter for a certain length of its course.

This could clearly be demonstrated in a patient who was for a long time suffering from pyuria, and whose clinical history I consider worth recording, because relatively early in the course of the disease a positive diagnosis could be arrived at by the finding of tubercle bacilli in the urine, and because the palpation of the thickened left ureter indicated the situation of the tubercular process on the same side.

Mrs. A——, aged fifty-three, felt—with the exception of an attack of pleurisy many years ago, from which she completely recovered—quite strong and healthy until her present ailments set in. She complained of a sharp, cutting pain on passing urine, and passed a small quantity of turbid urine at short intervals. The patient when I first saw her was still able to attend to her housework, although occasional fever and lack of appetite had already impaired her strength.

The physical examination revealed, in the left supraclavicular region, a slight dulness, diminished respiratory murmur, and a few râles. The thoracic organs showed no further abnormality. The liver and spleen were normal. On pressing the one hand beneath the free border of the ribs on the left side, and making counter-pressure with the other hand over the region of the kidney, posteriorly, letting the patient at the same time take a deep inspiration, I could easily feel a smooth, round, not fluctuating tumor. There was no dulness in the left hypochondriac region, since the tumor did not reach the anterior abdominal wall, but was covered by intestine. The dulness of the spleen could easily be made out, and thet umor was apparently from the left kidney. On the right side the lower portion of the enlarged right kidney could also be palpated. During this examination the patient felt no pain, and there was but little tenderness on pressure. The patient never complained of pain in the region of the kidney, but referred all her symptoms to the bladder. Palpation of the bladder through the abdominal wall was not painful, but on vaginal examination there was well-marked pain referable to the bladder—especially, the left side was very painful and thickened. Beginning at this thickening, the left ureter could be felt through the anterior and lateral wall of the vagina, for a distance of about an inch and a half, as a cord about the size of a goose-quill. On the right side the tenderness was trifling, there was no thickening, and the right ureter could be felt of normal size. The uterus was dextroverted, and showed nothing abnormal. Its appendages were healthy.

The daily quantity of urine was diminished, and its reaction was weakly acid. On some days the patient passed hardly three hundred cubic centimetres. The urine was cloudy, contained numerous caseous flakes, and on standing a sediment of white muco-pus separated. It contained a large quantity of albumin. On microscopic examination, the fresh urine contained numerous micro-organisms—partly bacilli, partly cocci—numerous pus-corpuscles, a few red blood-cells, fine granular, albuminous, and fatty detritus, much mucus, and epithelium from the bladder and pelvis. Besides these there were numerous hyaline casts. The surface of the urine on standing had a peculiar glittering and fatty appearance.

The lesion was undoubtedly a suppurative inflammation, involving the kidney, the pelvis, the ureter, and the left half of the posterior wall of the bladder. It was most probably on the left side, for this was indicated by the thickening of the left ureter and the left side of the posterior wall of the bladder.

The question now arose as to the cause of the suppurative inflammation, and whether the process had proceeded from the bladder to the kidney, or *vice versa*. Gonorrhœa or infection from a catheter could be excluded. No obstruction (stricture or caruncle of the urethra, stricture or tumor at junction of ureter and bladder) which might cause retention of urine and a subsequent suppurative inflammation could be demonstrated. The dextroversion of the uterus could hardly be the cause. A bending or compression of the ureter by changes in position of the uterus gives rise to hydronephrosis, the symptoms of which are different from those enumerated above. For a short time I thought of a calculus in the pelvis of the kidney, although no symptoms were present which could have justified this diagnosis in preference to that of a tumor or tuberculosis.

All diagnostic doubts whether it be an idiopathic abscess of the kidney, or a pyelitis calcarosa, or a malignant tumor or tuberculosis, were removed by the discovery of tubercle bacilli in the sediment of the urine. It was a

case of nephrophthisis with tubercular inflammation of the left ureter and wall of the bladder.

During the course of the disease moderate hæmaturia occurred on two occasions; besides this, there were all the symptoms which we are accustomed to find with phthisis—night-sweats, chills, fever, etc. The lesion of the lung, the cough, and the expectoration also became worse.

Repeated examinations showed an increase in the size of the tumor of the kidney, and an increased thickening of the left ureter, which could now be felt as a hard cord through the abdominal wall of the highly emaciated patient. The thickening on the left side of the posterior wall of the bladder had gradually spread to the right side. Obstinate diarrhœa finally terminated the sufferings, which lasted for one year and a half.

At the autopsy the lungs, kidneys, and intestines were examined. The lungs contained cheesy nodules, especially in the left upper lobe; but these were also found in the lower lobe, and in the right lung. In the lower portion of the small intestine, the solitary follicles and Peyer's patches were swollen and opaque; and scattered here and there were tubercular ulcers.

Of greatest interest were the kidneys; the principal changes were found in the pelvis and in the medulla of the kidney. The pelvis was dilated and contained cheesy nodules in its wall; on opening, a purulent fluid containing cheesy fragments escaped.

The tubercular process consisted principally in the formation of miliary tubercles, which coalesced more or less, and then had undergone cheesy degeneration without suppuration. The tubercular ulcers thus formed had, as a rule, infiltrated and ragged edges, and their bases were covered by a nodular, cheesy mass.

The larger part of the papillæ of the kidney was converted into a granular cheesy mass, while a large part of the medulla had also been involved in the process—a true phthisis renalis. Here and there larger or smaller portions of both pyramids and cortex were preserved, and, scattered in these, some few miliary tubercles could be detected. The portion of the kidney not destroyed by the tubercular process was in a state of fatty degeneration. Some portions had a peculiar lardaceous appearance and were more consistent; these gave amyloid reaction.

The left ureter was also involved in the process, and was at least three times as large as the right. Its mucous membrane had been converted into a granular surface, and was covered by a cheesy material. Small ulcers—broken-down nodules—could be seen in the fresh specimen, but these were especially well marked in the bladder. The bladder was thickened, principally on the left side, and was covered with nodules and ulcers. The ulcers arose in a similar manner to those in the bronchi and larynx. The infectious matter passing over the mucous membrane, infected it and produced the so-called lenticular ulcers. These were well marked in the fresh specimen. The lenticular ulcers were surrounded by a hyperæmic infiltrated area, and their base was in a condition of cheesy degeneration. They were chiefly situated in those places over which the urine passes, that is, in the base of the bladder, from the opening of the ureter to the commencement of the urethra. The tubercular process had advanced to the right side, and almost included the orifice of the right ureter. The right ureter and kidney were, however, not involved. The right kidney was in a state of fatty degeneration, and gave amyloid reaction. It was larger than normal, and this was probably due to compensatory hypertrophy.

My idea of the process is, that it first involved the pelvis or papillæ of the kidney, and then advanced downward to the bladder. The advance from the left to the right side of the bladder could be followed by repeated vaginal examination.

The question now arises, whether the tubercular inflammation of the kidney was primary, and secondarily affected the lungs, or *vice versa*. I believe that the kidney was secondarily affected from the lungs, owing to the fact that pleurisy had previously existed.

We distinguish a miliary tuberculosis of the kidney as an expression of a general miliary tuberculosis, and occasionally we find miliary tubercles in the kidney with pulmonary phthisis. These are emboli produced by tubercle bacilli, and are principally found in the cortex. They remain in the capillaries—preferably in the glomeruli. Differing from the disseminated tubercles in the cortex (which are always secondary), there also exists a primary tuberculosis, also called a local tuberculosis. This latter begins in the pelvis, calices, or papillæ of the kidney, and proceeds along the urinary passages, leading to nodule-formation and cheesy degeneration, and breaking down of the papillæ and medullary substance. This same form can, however, be produced in chronic pulmonary phthisis, probably by an embolus.

It would be a great error to suppose that the entrance of tubercle bacilli into the blood-current would always produce an acute miliary tuberculosis. This depends on the number of bacilli entering the blood, and on the power of resistance of the various organs. In secondary phthisis renalis we must suppose that the bacilli, instead of being deposited in the capillaries of the cortex, remain in the vessels of the pelvis, calices, or papillæ. It is a puzzling fact that in some instances of primary tuberculosis of the lungs, the secondary invasion of the kidneys takes place in the cortex; while in other instances the infectious material is deposited in the pelvis, or the papillæ. Most pathologists, so far as I know, attribute those secondary changes to embolism.

Another explanation, however, is probable. The bacilli may pass with the urine into the uriniferous tubules, and are then deposited from the urine on the walls of the tubules. In support of this latter supposition, we have analogies. In miliary tuberculosis we find tubercle bacilli in the urine. In experiments on animals, after injecting staphylococcus aureus into the veins, the same coccus is found in the urine. In ulcerative endocarditis the staphylococci are deposited from the blood on the valves. The valves must, however, have previously lost their endothelium. A denudation of epithelia of the uriniferous passages is doubtless a more frequent occurrence than is generally thought, as the urinary organs constitute the principal channels for eliminating deleterious and irritating material, ingested into, or formed in the body.

Since various authors[1] have drawn our attention to the possibility of palpating the ureters, I do not fail to examine my gynecological and pregnant patients on this point. In most cases—about eighty out of a hundred—one succeeds in palpating the one or the other ureter; most frequently the right, somewhat less frequently the left, and more seldom both at the same time. In pregnant women we can regularly feel one or the other, or sometimes both at the same time. The increased amount of blood and the increased succulence during pregnancy is naturally of great assistance in rendering the ureters more easily palpable. This also explains the reason why the ureters are more frequently palpated in multiparæ than in nulliparæ. A subinvolution of one or the other of the ureters seems to occur. Now and then patients come under my observation in whom there is a marked thickening of the ureter, and neither clinical history nor examination shows any disease of the urinary organs.

In palpating the ureters, I always prefer to place the patient on the back. The palpation is easy if the vagina is thin and flaccid. It is difficult or impossible if the vagina is tense and the tissue between the vagina and bladder highly developed.

The distance between the orifices of the ureters in the base of the bladder is one and a half inch, and about the same behind the opening of the urethra. The ureters then pass for about half an inch in the wall of the blad-

[1] Hegar: Kaltenbach's Operative Gynecology; Sänger: Arch. für Gynäkologie, xxix; H. Kelly: American Journal of Obstetrics, 1888.

der, upward and outward, reach the anterior vaginal wall near the os externum, and then pass upward and backward and outward into the base of the broad ligament. Here they pass behind and below the uterine artery, about midway between the pelvic wall and the lateral union of the vagina with the uterus.[1]

That portion of the ureter passing from the base of the bladder to the broad ligament, and even a larger or smaller portion of its course in the broad ligament, can in most cases be palpated, either in part or for its entire length, provided we are careful to make no great pressure in palpating, but merely glide the examining finger gently from side to side along the anterior vaginal wall, and begin half an inch above the urethral orifice. The ureters can be felt as distinct and movable cords of about one-half the thickness of a goose-quill. Confusion with arteries and nerves, with muscular bundles of the levator ani or obturator internus, with inflammatory contractions of the parametrium, or with diseased and anteriorly displaced tubes, is possible, but can easily be avoided if we take the anatomical and clinical features into proper consideration.

The changes which occur in the ureters are principally of two kinds. There may be a simple dilatation or an inflammatory (tubercular, etc.) thickening. The ureter may simply become dilated. If this be the case and the dilated ureter can be felt through the vagina, then the obstruction can only be below the dilatation, and may be caused by caruncle of the urethra, strictures or new growths at the orifice of the ureter, or impacted calculi. Dilatation of the vaginal portion of the ureter is rare.

As a rule, the thickening of the ureter is due to an advancing inflammatory process or new growth.

What value has the discovery of thickened ureters as regards diagnosis? The value lies therein that a thickened ureter gives us a clue that an advancing pathological process—either travelling from the kidney to the bladder or the reverse—is present. That a thickened ureter may occasionally be present without changes in the urinary organs, I have mentioned above. Exceptionally, pathological processes may also occur in the neighborhood of the course of the ureters, pass to the walls of the latter, and thus lead to thickening. But these are exceptions, which do not upset the rule that ureteritis is never a primary disease, but is always secondary to inflammations (tubercular, etc.) of the bladder, pelvis, or kidney.

The primary diseases are: cystitis, pyelitis, pyelonephritis, hydronephrosis, pyelitis calcarosa, tuberculosis, and tumors.

The physician has, for example, made the diagnosis of cystitis from clinical observation. On vaginal examination he finds both ureters as distinctly marked swollen cords. He is warranted in concluding that the inflammatory process has travelled upward, probably on both sides. Furthermore, this condition is also of prognostic value, in so far as ascending pathological processes on both sides present a serious prospect. Or the physician finds only the one ureter swollen, while the other is either normal or cannot be palpated. That the process is an ascending one can be accepted with great probability. But to assume that it has only advanced upward on the side on which the thickened ureter is present is not justifiable. It is well known that inflammatory processes often attack neighboring organs, skipping the interjacent tissue, so that we may have a cystitis and pyelitis without any involvement of the ureters. Thickened ureters have, accordingly, as regard the diagnosis, only a relative value. Their presence justifies the conclusion of an advancing process; but their absence does not warrant its exclusion.

I have, up to the present, spoken only of thickening caused by ascending pathological processes. That suppurative processes in the kidney or the pelvis rapidly infect the ureters and bladder is evident, since the latter are constantly bathed with infectious germs. That this, however, is not regularly the case, and that pyelitis may exist for some time without implicating the bladder, has been demonstrated by autopsies. To mistake a pyelitis for cystitis, and treat it as such, is not of seldom occurrence in practice. The presence of a thickened ureter has the advantage to draw our attention not only to the bladder, but also to the entire urinary apparatus. If the thickening be limited to the one side, then we have a very valuable index in determining the side on which the inflammation exists.

Finally, I would mention the relation of parametritic exudations and indurations to the urinary troubles of women. These are frequently referred to the bladder, while the real cause is in the upper part of the ureter and in the pelvis of the kidney, where retention of urine and inflammation exist. Large parametritic exudations may surround the ureter and compress it; chronic parametritis which has led to induration and retraction is liable to distort or bend the ureter.

In patients suffering from acute or chronic parametritis, and complaining of urinary troubles, the possibility of compression or torsion of the ureter and of retention of urine, with its consequences, must always be borne in mind. That portion of the ureter below the exudation may be collapsed, and in comparison with that of the opposite side cannot be palpated. There is a case recorded in which the ureter, owing to abolition of its function, became obliterated. Generally, however, the closure of the ureter due to compression or bending is incomplete, and most frequently intermittent. To draw conclusions, as regards the condition of the pelvis and kidney on the diseased side, from the impossibility to palpate the portion of the ureter beneath an exudation, while the ureter on the healthy side can be palpated, I regard as theoretically interesting, but as practically of no value. In palpation of the kidney we have a far better guide.

The palpation of the ureters, as I have undertaken to show, presents a valuable addition to our methods of examination, notwithstanding the restrictions which must be placed on its diagnostic value. Its value increases when used in connection with the usual procedure of examining—microscopic examination of the urine, catheterizing, temporary occlusion of the ureters, and palpation of the kidney.

CORPORAL DISINFECTION IN SCARLET FEVER AS A PREVENTIVE MEASURE TO ITS SPREAD.

By L. MERVIN MAUS, M.D.,

U. S. ARMY.

NOTWITHSTANDING the elaborate systems authorized and in force by National, State, and Municipal Boards of Health for the prevention of contagious diseases, it is only necessary to glance at the daily mortuary reports published throughout the country to note their general inefficiency. Though unsatisfactory in many particulars, public hygiene has done much to lessen at the present day the pestilential burdens with which humanity has been afflicted from the remotest antiquity. Small-pox, rightfully regarded at one time as the most fatal of the exanthemata, has sunk into comparative insignificance through the beneficence of vaccination. Typhus, ship, or jail fever has long since been relegated to the shades of the past through an intelligent appreciation of ventilation and necessary air-space; while its congener, typhoid fever, whose infective germ is most probably conveyed by a poisoned water-supply, may later on share a similar fate. Yellow and scarlet fevers, diphtheria, and measles continue, however, to defy the futile efforts of modern sanitation, and still present a bold front in the midst of our most advanced and enlightened civilization. In view of the recent strides in the etiology of disease a more flat-

tering prospect for the eventual subjugation of all infectious diseases by human intelligence lies before us. It has been satisfactorily established that scarlet fever does not originate *de novo* from certain atmospheric or telluric conditions, but is produced by a definite specific principle carried about from place to place. Many countries have been entirely free from it for centuries. It was not known in Europe until 1557, when it was introduced through the gates of Asia, nor did it make its appearance in America until 1735, when it was observed in New Hampshire. So slowly did the infection travel that it did not cross the Hudson River until eighty years later, nor appear as far south as North Carolina until 1830. Dr. Rush said, sixty years ago, that a physician would not likely see more than one case during a lifetime.

While the etiology of scarlet fever has not been thoroughly established by bacteriological investigation, yet there is a general professional concession that it originates from a specific germ, and that susceptibility to it is greatest during the period of desquamation, or when the detached cuticle is broken up and floats through the atmosphere laden down, as it were, with the infectious microbe. There is a unity, also, among the profession as to the method of its dissemination, all agreeing, as a rule, that the poison enters through the respiratory system, though, in a few instances, cases have been supposed to result from the ingestion of food, milk, or water containing the germ or infection; the latter may be probable, but is more than likely rare.

Scarlet fever may be communicated directly or indirectly; by personal contagion, or through the agency of infected clothing, books, letters, toys, hair, or other articles exposed to it. When it is communicated by personal contagion, the distance is usually limited to three feet or less. The non-susceptibility of many persons, when exposed to this disease, is most probably due to an accidental escape from inhaling air containing the germs. Familiar as we have been for many years past with the propagation and spread of scarlet fever, it seems rather strange that no effective system has been devised heretofore for its prevention. So far, instead of endeavoring to destroy the infection by chemical or germicidal measures, we have been satisfied with the more cowardly course of locking up or quarantining it; and consequently the individual who recovered from the disease was commonly sentenced to a dreary confinement of from four to eight weeks.

It seems quite rational to presume that a scarlatinous patient is surrounded by an atmosphere contaminated with the infectious microbe, since we know that an approach within a few feet or less of the patient is necessary to contract the disease by personal contagion. If this be true, we certainly are warranted in supposing that constant inhalation of this poisoned air is liable to increase the severity of the attack, and to keep up, as it were, a constant auto-infection. In view of this fact, it seems to me that a system of daily bodily disinfection would not only destroy the germs so as to prevent the spread of the disease to others, but would be a useful adjuvant to the treatment, inasmuch as through these applications the skin could be kept free from the poison, as well as the atmosphere the patient is compelled to breathe. This practice does away, in my opinion, with the necessity of prolonged isolation commonly enforced. So well am I satisfied with thorough and complete disinfection in scarlet fever, that I believe we can ignore isolation altogether in the mild cases, and ordinarily permit patients to join the family circle in ten days to two weeks—as a matter of course, the severity of the attack and the condition of the invalid being considered.

In presenting the following brief rules as preventive measures to the spread of this disease, I can say that this practice has been founded on personal experience, so far entirely satisfactory; I believe also that this treatment would be successful in the other exanthemata as a preventive measure.

1. Sponge the patient thoroughly morning and evening with a tepid solution of corrosive sublimate, 4 to 1,000, as soon as the eruption makes its appearance.

2. Wash the hair once daily with a solution of the corrosive sublimate, of the same strength, and also a solution of borax, 1 to 250.

3. Disinfect the urine, fæces, and expectoration, also the discharge, from the ears and nose, if there be any. A solution of the bichloride, 1 to 1,000 is best for this purpose.

4. As soon as the patient is permitted to leave the bed have the body washed with warm water and soap, then sponged with the 1 to 4,000 bichloride solution, wiped dry, and anointed with the following ointment:

℞. Sodii biboratis,
Zinci oxidi, ... āā ʒ iv.
Ol. gaultheriæ ..... ʒ ss.
Vaseline ..... ℥ iv.

The hair should be thoroughly washed with the bichloride and borax solution.

5. The patient is then to be enveloped in fresh and clean clothes throughout, and allowed to leave the sick-room if his condition otherwise admits of it.

6. The bed linen, soiled clothes, towels, etc., should be placed in a suitable sublimate solution and boiled, and the room well disinfected with sulphur. The sulphur candles are very convenient, and the disinfection should be repeated the second day, as the germs are very tenacious of life.

7. Require the nurse or attendant to keep the hair, face, and hands well disinfected during attendance, and to likewise make a complete change in his or her garments on date of the disinfection of the sick-room.

8. Continue the provisions of the third and fourth rules once daily until desquamation is complete.

The above method for the prevention of scarlet fever has proven very efficacious in my hands, and, though simple, warrants a fair trial by the profession. I think there need be no fear of corrosive sublimate poisoning, as a very minute quantity of the drug is liable to enter the system by this means. Other germicides may be used in place of the mercury, and it is probable that other eruptive diseases may likewise be treated with success in a similar manner.

Fort Porter, N. Y.

Œdema in Cancer of the Stomach.—M. C. Baert, of Brussels, writing in *La Clinique* on cancer of the stomach, calls attention to the frequency with which œdema of the ankles is met with in this affection after it has lasted a few months—a diagnostic aid which is by no means new, but is, he thinks, in danger of being too much overlooked at the present day. He gives a number of cases recently occurring in the various hospitals in Brussels, in which œdema was present. In one of these cases œdema came on as early as three months after the first symptoms of the affection made their appearance; in two other cases it was noticed after four months; but in most of the other instances it was delayed till the lapse of from six months to a year after the onset. In one case, where there was no evident cause to which to attribute the loss of appetite and the wasting complained of by the patient, Professor Carpentier, noticing some œdema of the ankle, diagnosed carcinoma of the stomach, and found his diagnosis confirmed by the appearance, a month afterward, of all the usual signs of the affection. Several of the cases presented a marked increase in the nitrogen excreted in the urine. With regard to the deficiency or absence of hydrochloric acid in the stomach, in cancer of that organ, M. Baert admits that it is usual, but agrees with Wolff and Ewald in saying that this sign is by no means peculiar to cancer, as it is found in other gastric affections.—*The Lancet*, April 13, 1889.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, June 22, 1889.

MEDICAL EDUCATION AND ITS CONTROL BY MEDICAL PARLIAMENTS.

THERE can be no doubt that the feeling among the profession of this country in favor of enforcing by law, if necessary, a higher standard of medical education is rapidly growing. It is seen in the constant reference to the subject at the meetings of medical societies and in our current journals. The fight is between some one hundred and twenty medical colleges and the thousand "professors" attached thereto on the one hand, and the medical profession at large on the other. The professors have had the advantage heretofore, because they have made it their special business to kill all obnoxious legislation, while the general practitioner, having no particular and immediate interests to defend, has let matters go on as they were.

Those who, like ourselves, have been contending for higher medical standards and removal of the licensing power from the men who confer medical degrees at $30 per head, are annually helped by the statistical and other work of Dr. John H. Rauch, of Illinois. It is well to confront our readers and the public often with the figures regarding our medical men and medical institutions.

There are now in the United States about one hundred and fifteen thousand doctors, or 1 to every 533.33 inhabitants. In 1880 the ratio was 1 to 601.12. The oft-quoted ratios of other countries are as follows:

Russia (in Europe)	16 : 100,000.
France	29 : 100,000.
Germany	32 : 100,000.
Austria	34 : 100,000.
United Kingdom	61 : 100,000.
United States	187 : 100,000.

We have 118 medical colleges in this country, and the ratio of medical schools to population in this and other countries is as follows:

Austria	1 : 6,032,421.
Belgium	1 : 1,384,163.
Denmark	1 : 1,969,039.
France	1 : 4,513,223.
Germany	1 : 2,350,000.
Italy	1 : 1,353,671.
Japan	1 : 1,716,920.
Norway	1 : 1,806,500.
Mexico	1 : 1,100,890.
Netherlands	1 : 1,015,142.
Portugal	1 : 1,449,517.
Russia (in Europe)	1 : 8,750,000.
Spain	1 : 1,662,586.
Sweden	1 : 1,526,300.
Switzerland	1 : 948,700.
United Kingdom	1 : 844,444.
United States	1 : 518,846.

With such competition among schools, and with their existence dependent upon matriculants, it is impossible that stringent requirements for graduation should be called for. Doubtless, if matters were left to take care of themselves, there would in time arise a general demand among the public for graduates of the best class of institutions. But the "supply and demand" argument is not entirely adequate. There will always be a majority of people quite incapable of judging as to the qualities of a safe and wise physician. They buy the goods most obtrusively thrust at them. For the protection of the public health, and for securing the greatest good to the greatest number, it is necessary to regulate the medical supply by some artificial means.

State Boards of Licensers and Examiners, with powers to prescribe the qualifications both of those who wish to become medical students and of those who wish to become physicians, appear to furnish the best available means for promoting this end at present attainable.

The work of some such a board as this in Illinois, as shown in the table, offers assurance of the utility of the method.

Comparison of the Total Number and Classes of Physicians in Practice in Illinois, July 1, 1877, and July 1, 1887.

	July 1, 1877.	July 1, 1887.
Number engaged in practice	7,400	6,180
Graduates and licentiates	3,600	5,704
Non-Graduates	3,800	476
Percentage of Graduates and Licentiates	48.6	92.3
Percentage of Non-Graduates	51.4	7.7

A modification of the Medical Examining Board was suggested by Dr. Osler in his address before the Medico-Chirurgical Faculty of Maryland. Dr. Osler proposed "the organization of the entire profession in each State into an electorate which shall send representatives to a central parliament, having full control of all questions relating to medical education, examination, and registration."

This means that the doctors of each State should elect their own medical board, and, under certain legal restrictions, regulate their own affairs.

"The powers of such a board," it is added, "would be accurately defined by legislation, and should relate, first, to preliminary education; secondly, to the examination and registration of candidates for the license to practise; and, thirdly, the control of allmatters relating to discipline with the profession. The necessary expense would be met—first, by the fees paid by the candidates for examination; secondly, by a small annual tax levied upon all registered practitioners. Such a body could look forward hopefully to a permanent establishment in each State, with buildings suitably equipped for examination, and with every possible provision for conducting, in an orderly and systematic manner, the business of the profession."

THE ETIOLOGY OF PUERPERAL ECLAMPSIA.

WRITERS continue to argue regarding the exact pathology of puerperal eclampsia. Recently Santos, of Buda-Pesth, and Pajot have argued that the convulsions are due, not to albuminuria, but to a reflex irritation starting in the uterus. Most physicians, however, will hold to the view that puerperal eclampsia is essentially uræmia, and that the convulsions are called out by the inflamed and inadequate kidneys causing poisons to be circulated in the blood. No

doubt the irritation of the uterine nerves acts as an exciting cause in some cases, while in others a predisposition to convulsive seizures exists, and the puerperal eclampsia is really an acute epilepsy.

The idea that puerperal eclampsia is usually only a modality of uræmia is the safest to hold. And M. Émile Blanc has recently contributed some facts to its support (*Lyon medical*, May 12, 1889). The observations were made under the direction of Professor Fochier at the obstetrical clinic, while the bacteriological studies were made at the laboratory of M. Arnoing, and with the help of M. Roux and Professor Boudet. We make these statements because the value of bacteriological work depends entirely upon whether the worker possesses skill, experience, and proper laboratory opportunities.

In 1887 M. Blanc found a microbe in the urine of an eclamptic which he cultivated, and which, inoculated into rabbits, produced convulsions. In February, 1889, he took the urine of another eclamptic woman, and with all possible precautions inoculated gelatine tubes. A peculiar micrococcus developed, having the form of a slender bacillus one to two micromillimetres long. He used the cultures to inoculate thirteen rabbits, two dogs, a guinea-pig, and a rat. In a large number of these there quickly resulted convulsions and, later, signs of acute nephritis. The blood and fluids were found to contain the same microbe, and cultivations of it caused also convulsive phenomena. Some animals in which no convulsions appeared developed albuminuria. Injection of sterilized cultures caused, in one case, albuminuria; in another, posterior paralysis.

The details of M. Blanc's work are not yet given; but he believes it to show that some cases of puerperal eclampsia are due to an organism which causes an infectious nephritis, and which itself appears to generate a convulsive poison. He does not seem to have tried to identify this microbe with any heretofore known.

THE MODERN TREATMENT OF LARYNGEAL TUBERCULOSIS.

A NUMBER of contributions have been made, more or less recently, upon the subject of the therapy of laryngeal tuberculosis.

Dr. W. Schleicher (*Ext. des Ann. de la Soc. de Méd. d'Anvers*, 1888) describes what may be termed benign forms of laryngeal tuberculosis. There are, he says, besides the ordinary types that accompany pulmonary phthisis, cases of laryngeal tuberculosis not associated with any lung disease. The patients simply suffer from hoarseness, pain, and cough, which after a time may disappear, for many of these cases are cured spontaneously. After a time, however, new ulcerations appear, which may be of a severe character but which are usually cured by treatment. The special point which Schleicher makes is that there are mild forms of laryngeal tuberculosis which do not need the severe treatment, such as curetting, lactic acid applications, incisions, etc. Schleicher reports eight cases, the diagnosis being made in most instances by finding the bacillus. The value of the observations depends, therefore, largely upon the skill of Dr. Schleicher in recognizing these organisms.

It is very true that the older opinion that laryngeal phthisis must always be preceded by pulmonary phthisis has been disproved. And other laryngologists, as well as Schleicher, are finding this laryngeal disease more frequent and more amenable to treatment than it was formerly thought to be.

In 1887 Professor Heryng, of Warsaw, asserted that out of thirty-six cases of tuberculous ulceration of the larynx twenty-seven had been cured. In eleven cases the cure was accomplished by lactic-acid applications; in the others, by curetting, and the application of iodoform emulsions.

Dr. Keimar, of Düsseldorf, looks upon Heryng's communication as epoch-making, and strongly indorses his lactic-acid treatment (*Deut. med. Woch.*, 1888, Nos. 46, 48, 51). He rubs upon the ulceration twenty, forty, fifty, and sixty per cent. solutions of the acid. In the severer cases and those with a sclerotic base, the curette is thought necessary. Dr. Keimar particularly urges the necessity for early diagnosis and treatment.

Dr. Sokolowski holds (*Wien. klin. Woch.*, 1889, Nos. 4, 5) a more sceptical attitude toward the subject of curability of laryngeal tuberculosis, especially by local measures. That it is sometimes curable spontaneously, or through local treatment, is true, but in cured cases new ulcerations develop later; and permanent improvement or cure are dependent very much upon the general condition and constitutional treatment of the patient.

Dr. Otto Seifert (*Wien. med. Wochenschrift*, 14, 15, 1889) brings up the subject of tracheotomy in laryngeal phthisis, reporting four cases. Dr. Seifert concludes that tracheotomy can cause an improvement and occasionally cure of the local trouble, that the life of the patient may be prolonged, and made more comfortable, and that the intensity of the pulmonary disease is no contraindication to the operation. These are views that should be accepted with caution. Tracheotomy in laryngeal phthisis is generally both useless and brutal.

The menthol treatment of laryngeal phthisis, as recommended by Rosenbach, has received some support from others, but it is probably much less useful than that by lactic acid.

News of the Week.

SUMMER DIARRHŒA.—The period has come when the well-to-do minority of physicians leaves the city, while the hard-working majority stays in town and writes articles on summer diarrhœa and related topics. Fortunately, something new is furnished us every year on these matters. We have passed from the stage of heat and sour milk as causative factors of summer diarrhœa; we are even leaving the microbe a little behind, and are dallying now with the ptomaïnes. The latest theory is one set forth by Dr. Ballard, in a report to the Local Government Board of England on the causation of the annual mortality from diarrhœa (*Lancet*). Dr. Ballard states his views as follows: "That the essential cause of diarrhœa resides ordinarily in the superficial layers of the earth, where it is intimately associated with the life processes of some micro-organism not yet detected, captured, or isolated. That the vital manifestations of such organism are dependent, among other things, perhaps principally, upon conditions of season, and on the presence of dead

organic matter, which is its pabulum. That, on occasion, such micro-organism is capable of getting abroad from its primary habitat, the earth, and having become air-borne, obtains opportunity for fastening on non-living organic material, and of using such organic material, both as nidus and as pabulum, in undergoing various phases of its life history. That in food, inside of, as well as outside of, the human body, such micro-organism finds, especially at certain seasons, nidus and pabulum convenient for its development, multiplication, or evolution. That from food, as also from the contained organic matter of particular soils, such micro-organism can manufacture, by the chemical changes wrought therein through certain of its life processes, a substance which is a virulent chemical poison; and that this chemical substance is in the human body the material cause of epidemic diarrhœa."

Sulphonal and Our American Laws.—Owing to competition among manufacturers abroad, the price of sulphonal in Germany is said to be only forty-five cents an ounce. In this country our law protects a foreign patentee, and Americans have to pay $2 per ounce for the drug.

The Queen and the London Physicians.—Our esteemed contemporary, *The Lancet*, has been experiencing depths of ecstatic feeling in a degree that is psychologically most interesting. It seems that the London doctors have had a statue of Queen Victoria made, and have set it up in Examination Hall. It was unveiled last month by the Prince of Wales, in the presence of eminent physicians and various members of the royal family; and Sir Andrew Clark made a speech. It was a very good speech, but not a very remarkable one. However, the *Lancet* is inexpressibly moved, and editorially exults over the remarkable talents of Sir Andrew, the unique condescension of the Queen in allowing her statue to be made, the graciousness of Royalty, and the in general supreme advantage of a monarchical form of government. The *British Medical Journal* gives a full-page picture of the statue. *The Hospital Gazette* received no invitation to the unveiling, however, is somewhat acidulous over the matter, and does not think so highly on monarchies.

Removal of a Laryngeal Cancer by Thyrotomy.—This operation has recently been done by Sir William Stokes, of Dublin. The patient was a man aged fifty-six, who had been suffering for eight months. Tracheotomy had been previously performed. The patient has been doing well.

Antipyrin Tippling.—It is said by druggists of this city, that the practice of going to a drug store and calling for ten grains of antipyrin has become a very prevalent one. In large drug stores there is a constant "run" on ten-grain antipyrin powders; in very much the same way that quinine used to be called for ten years ago. The practice of taking antipyrin systematically in any large amount cannot fail to be most injurious. Fortunately, for some reasons, the good effects of antipyrin as an anodyne are soon lost.

Sir William Jenner has received the Grand Cross of the Order of the Bath. This is said to be a particularly grand cross, and one which has never been conferred on a medical man before, with one exception.

The Dangers of the Suspension Treatment of Locomotor Ataxia.—Dr. Gorecki reports the case of a man, aged forty, who was suffering from a very acute form of the disease, and had become almost paraplegic; he read about the suspension treatment in the *Petit Journal*, obtained the apparatus, and had himself suspended by his man-servant for two or three minutes every day. For the first seven days all went well, and the patient noticed considerable improvement in his condition; but, after the eighth suspension, he was extremely ill, and lost speech and hearing. In spite of vigorous treatment, he grew rapidly worse, swallowing became impossible, sight was lost, the arms, and finally the thoracic muscles, became paralyzed, and he died in twenty-four hours, of suffocation. The accidental death in a suspension apparatus of Dr. Vincent, of Sharon Springs, has already been extensively noticed.

Death of Professor Breisky.—The death is announced, at the age of fifty-seven, of Dr. August Breisky, Professor of Gynecology at the University of Vienna. His death will be felt as a great loss to the Vienna Medical School.

Diphtheria and the Saloon Business.—The Paterson Board of Health has decided that where the placing of a green card on a house to indicate the presence of diphtheria on the premises would interfere with the business of a saloon-keeper, the card may be placed on the back door, where the general public may not see it!

The Johnstown Sufferers.—Dr. C. K. Mills and Dr. Thomas J. Mays, a Committee from the College of Physicians of Philadelphia and the Philadelphia County Medical Society to carry relief to the medical practitioners, sufferers by the flood, reached Johnstown on Monday. They found that six physicians were drowned and twenty-one had lost all they had. They will immediately expend about three thousand dollars in the work, which has been subscribed by the profession of Philadelphia, and more money will be raised to continue it if required.—*Medical News.*

Tendon Grafting.—Mr. Mayo Robson, of Leeds, has recently shown that tendon can be successfully transplanted and grafted. In a case reported all the tendons of the back of the hand were torn away, and a hanging tendon from the ulnar side of the palm was stitched to the extensor muscle of the fingers at one end and to the remaining fragment of the extensor tendon on the dorsum of the index-finger. It retained its vitality, and subsequently allowed nearly as efficient movement of the finger as the man had before enjoyed at his work as a weaver.

The Death of Dr. Harrison Teller occurred at Mount Kisco, N. Y., in the seventy-sixth year of his age. He received his license in 1837 from the Westchester County Medical Society.

The New Officers of the Westchester County Medical Society.—The following were elected at the Ninety-first Annual Meeting of this Society, on June 18th: *President*—Samuel Swift, of Yonkers; *Vice-President*—Charles Mason, of Peekskill; *Secretary*—William Frank Green, of Mount Vernon; *Treasurer*—Robert Thomas Howe, of Mount Vernon; *Curator*—Newton Freeman Curtis, of White Plains.

NEW HAMPSHIRE MEDICAL SOCIETY.—The Ninety-eighth Anniversary of the Society was held in Concord, Monday and Tuesday, June 17th and 18th, at the hall of the G. A. R., 15 Warren Street, commencing at 11 A.M., Monday, June 17th.

THE NORTH TEXAS MEDICAL ASSOCIATION met in Paris, Tex., Tuesday, Wednesday, and Thursday, June 11th, 12th, and 13th.

NEW YORK INFANT ASYLUM, MOUNT VERNON, N. Y.—Dr. Charles G. Kerley has been appointed Resident Physician at the New York Infant Asylum, Mount Vernon, *vice* Dr. C. E. Kimball, resigned.

TO CURE SNORING.—The following suggestively effective remedy is offered in answer to the physician's wife who asked for a remedy for a snoring husband: Raise yourself softly on your elbow, and gently but firmly bite his nose.

NEW YORK POLYCLINIC.—The following new appointments have been made at the New York Polyclinic: Dr. Thomas R. Pooley, Surgeon in Chief of the New Amsterdam Eye and Ear Hospital, Ophthalmic Surgeon to the Sheltering Arms, Consulting Ophthalmologist to St. Bartholomew's Hospital, Professor of Ophthalmology; Dr. B. Sachs, Consulting Neurologist to the Montefiore Home for Chronic Invalids, Professor of Neurology; Dr. L. Emmett Holt, Consulting Physician to Hospital for Ruptured and Crippled, Professor of Diseases of Children (Visiting Physician to the New York Infant Asylum); Dr. August Seibert, Physician to the Children's Department of the German Dispensary, Professor of Diseases of Children; Dr. H. Marion Sims, Gynecologist to St. Elizabeth's Hospital and New York Infant Asylum, Professor of Gynecology; Dr. William H. Fluhrer, Surgeon to Mount Sinai and Bellevue Hospitals, Professor of Genito-urinary Surgery. The Polyclinic has increased its hospital facilities by the purchase of a large building immediately adjoining its original property, and after making necessary changes will furnish and have it open by September 16th, when the regular session will commence.

THE TENEMENT-HOUSE AS A HEALTH-RESORT.—According to a report on the mortality of this city recently made to the Board of Health by Dr. R. S. Tracy, the mortality of our tenement-house population is considerably less than that of the general population, the figures given being as follows: Total population, 1,526,081; total deaths, 40,175; tenement population, 1,093,701; tenement deaths, 24,842; general death-rate, 26.33; tenement death-rate, 22.71. To bring up the average, it follows that the death-rate among the population not living in tenements must be about twenty-eight per thousand. The results of the investigation are summed up by Dr. Tracy as follows: "The death-rate in tenement-houses is less than the general death-rate of the city. The death-rate in the large tenement-houses is less than in the smaller ones. That while diarrhœal diseases and diphtheria show a greater death-rate in the larger houses (leaving the suburban districts, where the conditions are very different), phthisis and pneumonia show comparatively little difference, that difference, however, being in favor of the larger houses. The greatest general death-rate among persons over five years of age, the next to the highest death-rate from diarrhœal diseases and pneumonia, and markedly the highest from phthisis, are in the district south of Fourteenth Street and west of Broadway. The excessive mortality in this part of the city is probably connected with the great number of old houses and the dampness of the soil. These results are much at variance with what was expected. It seems to be sufficiently established that people do not live under such extremely bad sanitary conditions in the tenements as they have been supposed to."

RUSH MONUMENT COMMITTEE.—The Rush Monument Committee will meet in the right gallery-room, at Music Hall, Newport, R. I., on Tuesday, June 25th, at 1 P.M., immediately after adjournment of the morning session of the American Medical Association. The attendance of others interested in the project is invited. Collections and subscriptions should be forwarded to the Treasurer, Dr. Joseph M. Toner, 615 Louisiana Avenue, Washington, D. C., before June 15th. Albert L. Gihon, M.D., Chairman R. M. C.

NEW YORK POST-GRADUATE MEDICAL SCHOOL.—The summer term of this institution commenced on June 17th. The fees for this session are one-half those of the winter term, and yet the advantages in the dispensary of the school, and in many of the hospitals of the city, are quite as good as during the winter.

Obituary.

JAMES ETHELBERT MORGAN, M.D.,

WASHINGTON, D. C.

DR. JAMES ETHELBERT MORGAN, Emeritus Professor of Materia Medica in the Medical Department of Georgetown University, died in the city of Washington, June 2, 1889.

Dr. Morgan was born in St. Mary's County, Maryland, September 25, 1822. In 1845 he settled in Washington, and continued in the active practice of his profession until within a few months of his death. Coming to the city in the earlier days of its history, he grew up with the place, becoming widely known, and possessing for years the highest confidence and esteem of the oldest and best residents, many of whom have been his devoted friends. Although mainly distinguished in the line of general practice, he contributed numerous articles upon medical topics to the literature of the day. His "Defence of Medicine and of the Medical Profession," an oration delivered before the Medical Society of the District of Columbia about five years ago, was a powerful and philosophic plea for the value of drugs in the curing of disease. He had been President of the Medical Association, and of the Medical Society of the District of Columbia. He was consultant in the Columbia Lying-in Hospital, and in the Central Dispensary, and for many years was a member of the Judicial Council of the American Medical Association.

With Dr. Robert King Starr, he was appointed to investigate the causes of the celebrated National Hotel disease, an epidemic of historical importance, which occurred in 1859, as will be well remembered by our older readers.

A finished classical scholar, Dr. Morgan retained his fondness for this study until the last.

He leaves a widow and six children—three daughters, one of them the wife of the Hon. Emory Speer, United States Judge for the Southern District of Georgia, and three sons, two of whom, Dr. Ethelbert Carroll Morgan and Dr. J. Dudley Morgan, are physicians practising in Washington.

Personally, Dr. Morgan was of commanding figure, fine address, and great geniality of disposition; a devoted physician, a courtly gentleman, and a man whose sterling qualities of mind and heart were recognized by all.

Society Reports.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, February 13, 1889.

(Continued from p. 446.)

WILLIAM P. NORTHRUP, M.D., PRESIDENT, IN THE CHAIR.

DR. L. EMMET HOLT presented a larynx showing

ULCERATION OF THE VOCAL CORDS FOLLOWING MEASLES.

The patient was admitted to the Randall's Island Hospital in June in wretched condition, at that time one year of age. She gained in weight and improved steadily until she took measles, January 5th. The rash came out well and the constitutional symptoms were of only average severity. She did well until January 17th, when hoarseness, nasal discharge, and a rise of temperature led to the suspicion of diphtheria, although no membrane was visible anywhere. From this time until death, which occurred January 25th, she had loss of voice, considerable laryngeal dyspnœa, and, in fact, all the usual symptoms of membranous laryngitis. She was not operated upon, although the dyspnœa was so severe that it was contemplated several times. She emaciated steadily and died of exhaustion apparently. Throughout the last week of the illness there was considerable choking whenever the attempt to swallow fluids was made.

Autopsy.—Brain not examined. Larynx: The vocal cords were completely destroyed by ulceration, which extended upward to the ventricles of the larynx and downward for nearly one-fourth of an inch. The ulcer went apparently down to the cartilages. Its surface was covered with a ragged mass of necrotic tissue. It had all the appearances of being of recent formation. The larynx otherwise showed no noteworthy change. No false membrane in larynx, trachea, or bronchi. Lungs: The right contained several old, cheesy nodules, the largest being the size of a walnut. Nothing recent in either lung, and no pleurisy.

There was nothing of interest or importance seen in liver, spleen, kidneys, stomach, or intestines.

Dr. Holt also presented a specimen of

CYSTIC DEGENERATION OF THE KIDNEY.

The patient was a female in middle life who died of chronic suppurative peritonitis, having been under operation only a few hours before death. The right kidney was enlarged—weight, five ounces—and presented the usual appearances of chronic diffuse nephritis, quite well marked; the capsule was adherent, the surface granular, and the cortex a mottled yellowish-white color. The right kidney weighed one ounce; it was made up of cysts, the largest of which were about three-quarters of an inch in diameter. It was enveloped in fat, and on section very little renal tissue was seen. Dr. Holt had not made the autopsy, but in the specimen as shown there had been found no ureter. The heart was also shown. It exhibited the lesions of well-marked mitral stenosis, the orifice not admitting one finger.

DR. BIGGS did not think that the specimen was one of congenital cystic kidney. He asked if the speaker had ever seen any other congenital cystic kidney of such small size.

DR. HOLT said that he had presented one to the Society some time ago weighing only about half an ounce. He had also seen another one that was very small. He had supposed that this one was congenital from the fact that no trace of a ureter could be found.

THE PRESIDENT had seen several cases of ulceration of the vocal cords in children, but had never been able to account for them satisfactorily. He believed that Dr. Holt's case was one of diphtheritic ulceration.

DR. H. M. BIGGS presented some specimens illustrating

TUBERCULOSIS OF THE FEMALE GENITAL ORGANS.

The subject was a woman, fifty-seven years of age, who had died in Charity Hospital a short time after admission. The abdomen was noticed to be slightly distended, and the patient had had an irregular temperature, reaching at one time 101.5° F. The clinical history was otherwise incomplete. At the autopsy, evidences were found of recent tubercular peritonitis with little or no exudation. In the lungs scattered tubercles were seen, and at the apex of one lung was a rather large cheesy nodule. The uterus was somewhat distended, and, on being cut into, was found to be filled with caseous matter. Both Fallopian tubes were dilated, the dilatations being nodular. A cheesy mass was also found in the right ovary. Tubercle bacilli were present in large numbers in this caseous material.

These cases of tubercular disease of the female genital organs, the speaker said, do not seem to be recognized, in this country at least. There should not, however, be the slightest difficulty in making a diagnosis, for the discharge contains bacilli in great numbers. The disease, furthermore, could not be so very rare, for he had seen four cases within the past year. In three of these cases the process seemed to be older in the genital organs than anywhere else.

A second specimen was one of

GUMMY TUMORS OF THE BRAIN,

illustrating the symmetry of the lesions of syphilis in this organ. The patient presented symptoms of tertiary syphilis, and some months before death he developed ophthalmic paraplegia—double ptosis. As a result, probably, of this, he fell while going down-stairs, and broke his skull, death resulting. At the autopsy a gummy tumor was found on each third nerve, and there was also a slight thickening about the infundibulum and about the fissure of Sylvius on each side.

Dr. Biggs also presented a third specimen, showing

IMPACTION OF A GALL-STONE IN THE CYSTIC DUCT,

completely obliterating the duct. Afterward the fluid contents of the gall-bladder had been absorbed, and the bladder-walls had contracted down, closely embracing the contained calculus. There had been no symptoms occasioned by this condition; none, at least, during the time that the patient had been under observation. Death resulted from the rupture of an abdominal aneurism.

DR. W. P. NORTHRUP presented the

GIZZARD OF A FOWL IN WHICH WERE THREE PINS.

The pins were found when the chicken was being dressed for the table. They were very firmly embedded in the walls of the gizzard, and could not be pulled out with the unaided fingers.

The Society then went into executive session.

Stated Meeting, February 27, 1889.

WILLIAM P. NORTHRUP, M.D., PRESIDENT, IN THE CHAIR.

DR. GEORGE C. FREEBORN presented some specimens showing

CARCINOMA OF THE CERVIX UTERI, FIBROMA OF THE UTERUS, AND OCCLUSION OF THE LEFT URETER BY A CARCINOMATOUS MASS.

The patient, a woman, about thirty years of age, was attacked, shortly after her admission to the New York Cancer Hospital, with severe vomiting. Soon after that she had a severe convulsion. Alternating attacks of vomiting and convulsions continued for three days. The patient finally died in a convulsion. The examination of the urine during this time was negative.

Autopsy.—The brain was slightly œdematous, but otherwise normal. The thorax was not examined. The stom-

ach, liver, spleen, and intestines were normal. The right kidney was slightly enlarged, and showed the gross lesions of chronic diffuse nephritis. The left kidney was about normal in size, and showed the same lesions as the right. Its pelvis was dilated to twice the normal size. The left ureter was dilated throughout its entire course to the base of the bladder, where it was lost in a mass of carcinomatous tissue. It measured 1 ctm. in diameter, and was filled with urine. The uterus was enlarged, measuring 12 ctm. in length, and 8 ctm. across the horns. The ovaries were slightly enlarged, cystic, and bound down to the uterus by adhesions.

Upon making an antero-posterior section through the uterus and upper part of the vagina, it was found that the cervix uteri was almost completely destroyed. The posterior wall of the vagina was infiltrated with a dense, diffuse mass. A portion of this mass extended into the wall of the bladder, in the shape of a conical projection, measuring 1½ ctm. in height, and 2 by 3 ctm. at its base. The apex of this mass pressed upon the left ureter, completely occluding its lumen as it passed into the bladder. The mucous membrane of the bladder over this mass appeared normal.

At the fundus of the uterus, attached to the left wall, and filling up the entire cavity, was an oval mass. On section the mass measured 4 by 4½ ctm. It had a white, glistening appearance and was quite hard.

Microscopical examination.—Sections from the cervix uteri and from the mass infiltrating the vaginal wall showed the growth to be carcinoma of the epitheliomatous type. Sections from the uterine tumor showed it to be a fibroma.

Dr. Eugene Hodenpyl presented some specimens showing

INFLAMMATION AND GANGRENE OF THE VERMIFORM APPENDIX.

According to the patient's own account he had been in perfect health up to four days before his admission to the hospital. He then began to complain of pain in the right inguinal region, and presented other symptoms of perityphlitis. Examination revealed the presence of pus in the right iliac fossa, and a small incision, two and a half inches long, was made to give exit to it. The patient was, however, not relieved, and died shortly afterward.

At the autopsy the lungs were seen to be intensely congested. The abdominal cavity contained about two quarts of pus, and the intestines were more or less covered by adhesions. The vermiform appendix was distended, and in a condition of commencing gangrene. The pus surrounding the appendix had burrowed up behind and around the right kidney, and its effects were shown by a necrotic condition of the fat. The left kidney presented the lesions of parenchymatous nephritis. The specimens showed these lesions, and also a part of the abdominal wall, in which the incision was made down to the seat of disease.

In reply to a question as to the length of time that the disease had existed, Dr. Hodenpyl said that, according to the patient's statement, it was only four days, but he thought the time must have been longer than this.

Dr. Lewis Hall Sayre presented a

TUMOR OF THE BREAST,

together with an enlarged axillary gland, removed from a negro woman about sixty-five years of age. Some five or six years ago the patient had first noticed a slight swelling in the left breast, accompanied by lancinating pains, and this had continued to grow slowly. She was a washerwoman, and had followed this occupation up to the day before the operation was performed. The breast was removed by an elliptical incision, the only thing worthy of remark about the operation being the difficulty experienced in bringing together the edges of the wound by reason of the large amount of tissue that had to be removed. The only gland that appeared to be affected was one in the lower part of the axillary region, well under the pectoralis major muscle. This was removed, and was shown with the breast. The tumor was apparently a carcinoma, and Dr. Sayre asked that it be referred to the Committee on Microscopy for examination.

Dr. William P. Northrup presented some specimens, removed from a child aged five weeks, showing the

ARREST OF DEVELOPMENT OF ONE KIDNEY.

The specimen showed the mere rudiments of the left ureter, at the extremity of which was a bulbous tip, 1 ctm. long by 2 mm. in breadth, representing the undeveloped kidney. The speaker had previously presented two cases of displacement downward of the kidney, and in each case, as in this, it was the left kidney that was concerned. In both these cases the suprarenal bodies were in their normal position. The child from whom this specimen was removed had presented no symptoms directing attention to the kidneys. The ureter had evidently not increased in length for some time, though there had been some enlargement of its calibre. The rudiment of the kidney was lying on the left common iliac artery at the level of the last lumbar vertebra.

Dr. Messenger asked whether there was any arterial supply to the rudimentary kidney.

Dr. Northrup had been unable to discover any vessels, even rudimentary ones.

Dr. J. C. Peters said that one of the first specimens examined microscopically in this Society was one similar to this, and he thought it would be interesting to compare the results of an examination in the present instance with what was observed in the other.

The Society then went into executive session.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON PEDIATRICS.

Stated Meeting, March 14, 1889.

J. Lewis Smith, M.D., Chairman.

A CASE OF LARYNGISMUS STRIDULUS AND ECLAMPSIA ASSOCIATED WITH RACHITIS.

Dr. H. W. Vineberg read the history of the case, which was prefatory to a paper on the subject. The child was nine months of age, born in normal labor, and, until laryngismus stridulus developed at the sixth month, gave a fair history. At the outset of the attacks they were repeated three or four times a day, later they were not so frequent, they began to terminate often in a convulsive seizure, and the convulsions sometimes occurred independent of the laryngeal symptoms. The only additional symptom was marked constipation. The mother said the child sweat freely about the head. When Dr. Vineberg saw the patient its muscles were flabby, it was anæmic, the liver and spleen were enlarged, the cranial bones were not softened, but there were indications of rachitic constitution. The principal treatment was at first regulation of the diet and hygienic instructions, but the patient did not improve until he had given bromide of potassium. While taking this no attacks occurred, but when it was used up there were two spasms of the larynx. The bromide was again ordered, and the attacks ceased.

In his paper the author referred to the views of different men on the causation of the attacks, and said that swelling of the thymus gland had once been rejected as a cause, but lately Dr. Jacobi had expressed the view that it was sometimes the exciting cause. Many admitted the frequent accompaniment of rachitis, and he had himself never seen a case, except in rachitic children. Laryngeal spasm was most frequent between the fourth and twenty-fourth month of life, and was much more common in boys than in girls. Irritation in any part of the body might precipitate an attack. It was usually accepted that enlarged tracheal and bronchial glands might act as the pathological factor through irritation of the vagi. The

diagnosis was easy, the prognosis was grave, the majority of severe cases proving fatal. Death might occur during an attack, by intercurrent disease or gradual exhaustion. There could be no doubt, however, that many infants suffered from a milder form of the affection, recovered, and were not seen by the physician. The author related such a case, seen by him for another affection.

The treatment related to the attacks and the intervals. If the attacks were mild they passed off so soon that nothing could be done. If they were severe the child should be set in warm water, while cold water was applied to the upper part of the body. Tickle the fauces with the finger to start vomiting. If this did not succeed, nothing would act quickly enough, unless it were apomorphine hypodermatically. It was too dangerous to trust the use of chloroform or ether to the mother. The treatment between the attacks related to diet, general hygiene, removal of sources or irritation, overcome constipation; of drugs, those most used were bromide of potassium, musk, and belladonna. Rickets in some form were usually present, and in addition to other treatment phosphorus should be given in cod-liver oil.

DR. VINEBERG also related

A CASE OF TETANY IN A CHILD.

The child was then fifteen months of age, and several times during life had had mild attacks, during which it caught its breath, and on one occasion the breathing stopped, the eyes became suffused. Later the feet took on spasmodic contracture, assuming the position of valgus, and there was contracture of the fingers of both hands. Thus the child had suffered from laryngismus stridulus and tetany. He believed the latter affection was rare in children.

DR. A. JACOBI said the cause of spasm of the glottis must be looked for in some irritation of the recurrent laryngeal nerve through which it was innervated, or indirectly of the pneumogastric. That irritation might be local or peripherous or central. If peripherous, it might be in the stomach, which was supplied by the pneumogastric. The recurrent might be irritated by a mediastinal tumor, by an enlarged bronchial gland, or it might be pressed upon by a large thymus gland. In children the space between the manubrium sterni and the spinal column was very narrow, considering the vessels which passed through it, and it was quite reasonable to suppose that swelling of the thymus, which in some children was of some size, might press upon and irritate the recurrent nerve. There was clinical evidence to prove this. He believed forty-nine out of fifty cases of laryngismus stridulus occurred in rachitic children. He showed the bones of the skull in such a case, illustrating the marked softening, usually with thinning, which took place in their structure, and said there was a condition of hydrocephalus, with or without much effusion, and one need not wonder that in such a condition there should be peripheral irritations. The temporary congestion, or anæmia at the root of the nerve supplying the glottis, might excite a spasm, and it was to be noted that the commencement of the attack was one of paralysis, and the crowing noise took place when there was reaction.

Introducing the finger down the throat during the spasm served another purpose besides that of exciting vomiting, although this latter was important. It caused the tongue to roll from off the glottis, which it might obstruct by being partially swallowed if long and free. The case of tetanic spasms related by Dr. Vineberg, showed that the source of irritation was not always the same.

THE CHAIRMAN had seen three cases of tetany in children within two months recently, while he had not seen more cases within three years previously. In all there was a history of intestinal irritation.

DR. C. H. MAY then read a paper entitled

SCARLATINOUS OTITIS.

DR. SAMUEL SEXTON opened the discussion, and directed his remarks chiefly to the question of treatment, which was the same as in otitis from other causes or accompanying other diseases. He prefaced his remarks by describing some anatomical specimens, illustrating the different locations of the inflammation. The treatment varied according to the location. The least common, but most important situation, was in the upper part of the tympanum, in the attic of the ear, beyond the reach of vision. Here, if the drum-head were perforated in the direct line, it would give no exit to pent-up matter. Use a curved knife, pass into the upper posterior quadrant, cut down to the bone. It was more difficult than direct puncture in the lower posterior quadrant. The child should be chloroformed, good illumination should be obtained, best by the electric light. If there were inflammation about the ear, it was usually best to incise down to the bone. He had not for many years applied leeches, blisters, or iodine. Syringing once or twice a day, at least in the acute stage, was often enough. He thought there was usually too much poulticing. He thought the exudation often described as diphtheritic was not really diphtheritic. After drainage was established he gave minute doses of aconite, largely diluted with water, or of gelsemium. If an anodyne were called for, it should be in liberal quantity, as small doses seemed to increase the pain. Deafness was more likely to result from adhesive inflammation than from destruction of the drum-head. There might even be loss of the ossicles, with destruction of the drum-head, and hearing still be preserved. He thought sympathetic irritation from the teeth was often a cause of increased aural inflammation.

DR. GRUENING thought with the author that incision of the drum-head should be made at an early stage. The operation was a simple one, and to go into refinements when addressing the general profession was uncalled for. He did not use leeches nor iodine, nor did he employ Politzer's method in children, as it was likely to do more harm than good. Neither could the Eustachian tube be catheterized in these patients. Matter could be better pumped out than syringed out from behind. He thought it preposterous to speak of dentition in connection with otitis media in scarlatina.

DR. O. D. POMEROY thought it all important to prevent at the outset, if possible, a formidable attack. It was very well to cut the drum-membrane after the cavity was distended, but what was more desirable was the prevention of pus-formation. The cause of deafness was more likely, in his opinion, to be secondary labyrinthine changes than anything else. The physician should seek to diminish excessive hyperæmia early in the case. For this purpose he was sure leeches were of value. He used the aural douche, even before perforation of the drum-membrane, as it reduced hyperæmia and relieved pain. It did not macerate the parts as poulticing did. The water should contain a little salt, to render it non-irritating. Then he made warm applications to relieve pain; the rubber bag, made almost hot, had a delightful effect. Water for syringing the ear should be too hot for the hand. One gentleman had said that after rupture of the drum-membrane Politzer inflation should not be practised. He would, he said, sit down on that with all his avoirdupois. As to cutting down on the mastoid, he was accustomed to cut down on the apex of the swelling, wherever located. Boracic acid should not be used in acute suppurative otitis, as it acted as an irritant. In some chronic cases it acted better than anything else.

DR. T. R. POOLEY did not think otitis occurring during the course of scarlet fever possessed any distinctive characters which warranted the use of the term "scarlatinous otitis." He did not think it advisable to add another name to the nomenclature. In treatment of the acute affection the most important element was rest. But children with scarlatina were likely to be quiet in bed any way. Next in importance was local extraction of blood. This would often obviate the necessity for perforating the drum-head. Next in importance was the instillation into the ear of water as hot as it could be borne. He used the

ordinary medicine dropper. Paracentesis was called for where there was bulging of the drum-head. He was thoroughly in accord with those gentlemen who said that the use of either the catheter or Politzer method was injurious in acute inflammation of the middle ear. The sudden impact of cold air did harm. Cleansing was best effected by the syringe.

Dr. Gruening explained that he did not favor the use of leeches in scarlatina otitis, because of inability to exactly regulate the amount of blood lost. This was less important in other cases, and there he applied them.

In closing the discussion, Dr. May said he used Politzer's bag only where there were symptoms indicating retention in the middle ear.

Dr. A. Brothers then read extracts from his paper,

REPORT OF ONE THOUSAND CONSECUTIVE CASES OF DISEASES OF CHILDREN, WITH SPECIAL REFERENCE TO TREATMENT.

The cases were treated in the outdoor department of Bellevue, extending from April until December of last year. He stated incidentally that he believed the dispensaries, owing to lack of suitable arrangements, often acted as centres for the spread of contagious diseases. Salol was a failure in the gastro-intestinal troubles. The urine was best collected in children by the use of a small, semi-elastic catheter. There was an interesting case of death from purpura hemorrhagica in a child which had almost completely recovered from an attack of gastro-duodenitis. Phosphorus in oil had proven of speedy benefit in rickets.

The Section adjourned by limitation.

SECTION ON NEUROLOGY.

Stated Meeting, April 12, 1889.

Landon Carter Gray, M.D., Chairman.

DISCUSSION ON NERVOUS SYMPTOMS ARISING FROM OVARIAN DISEASE, AND THEIR TREATMENT.

Dr. C. L. Dana opened the discussion, giving an outline of the points which he thought should be brought up, and expressing his own opinions as far as he had been able to form any from observation.

He took ovarian irritation to mean, not anything like irritable heart or irritable stomach, but a condition of the ovary which produced general or certain remote symptoms by reflex influence. He did not think it was intended to discuss the question of ovarian irritation which manifested itself as a neuralgia. One question for discussion was the anatomical basis for the ovarian irritation. It was claimed, he believed, that in ovarian irritation there need be simply some nervous or physiological change, not a gross anatomical alteration. Charcot seemed to hold that in ovarian hyperæsthesia there might be only a functional change producing a general neurosis. When an anatomical change was present, by far the most common was hyperæmia and chronic ovaritis. These were so much more frequently alleged as causes of the symptoms that parenchymatous diseases, cysts, and malignant tumors might be left out of the discussion. The latter did not seem to cause the symptoms commonly attributed to irritated ovary. He had found in printed works a great many different diseases attributed to ovarian reflexes. For example, such vaso-motor disorders as irritability of the heart, and angina-like attacks, hystero-epilepsy, mania, melancholia, neurasthenic states, as sciatica, insomnia, dyspepsia, intercostal neuralgia, bladder and rectal pains. These and other disorders had been ascribed to ovarian irritation; more especially, he believed, to chronic ovarian hyperæmia and inflammation.

The question arose, in what degree these indirect, or perhaps he should say direct, so-called ovarian reflex disorders were really due to the ovaries. His own opinion was, that if an ovary were healthy it could not produce such disorders; that was, if it contained no anatomical changes. He did not believe there was any proof that functional change in the ovary was the starting-point of hysterical convulsions, epilepsy, chorea, etc. Nor did he believe that chronic ovarian hyperæmia and chronic ovaritis could produce any of the severe constitutional neuroses of themselves; their influence in the production of such neuroses had been very much over-estimated. Furthermore, he did not believe that removal of the ovaries cured the neurosis in any degree comparable to other measures, and it seemed to him that such practice was, on the whole, unscientific as well as unsuccessful. Exception might be taken to his conclusions, but they were based on reasons like the following: (1) The nervous diseases mentioned (convulsive hysteria, epilepsy, mania, etc.) usually occurred in persons with perfectly healthy ovaries; (2) the ovaries might be moderately or very markedly diseased without any such symptoms; (3) the removal of the ovaries had not been attended by any great success in the cure of such neuroses. In support of his views Dr. Dana analyzed some of the statistics of removal of the ovaries in patients subject to hystero-epilepsy, etc., among others those of Battey, and claimed that the conclusions of some were not justified by the facts. Hysteria was a brain disease; in it the patient showed a tendency to direct the mind to some pathological process, and usually in women it was to the pelvic organs.

Dr. Dana concluded by saying that the tripod of life was the brain, the stomach, and the pelvic organs. In the stomach was manifested the instinct which preserved the individual; in the pelvic organs, that which preserved the race; and in the brain, that which perpetuated those qualities distinctive of man—the spiritual and the intellectual faculties. Neuroses were largely peculiar to man, and it was a mistake to so commonly attribute them to organs characteristic of both man and beast.

Dr. W. Gill Wylie read a brief paper, expressing his views on the subject under discussion. He was inclined to think that the influence of the ovaries in producing reflex nervous symptoms had been overrated. Diseased ovaries were likely, in delicate, nervous women, to produce reflex symptoms, while women with a well-balanced nervous system might go about with diseased ovaries without ever having definite reflex symptoms due to such disease. Imperfectly developed women almost invariably had imperfectly developed uterus and ovaries, and were more likely than their sisters to have uterine and ovarian disease, and also disease of the nervous system.

He had nearly always found chronic uterine and ovarian disease complicated by an abnormal condition of the rectum or colon, and he had obtained some brilliant results in nervous disorders, supposed to be due to uterine or ovarian disease, by treatment directed to the rectum and colon.

In patients with mental disturbances he always sought the advice of an alienist. If other measures failed to allay symptoms, laparotomy should be considered. Certain forms of ovarian disorders might be rendered latent by local treatment, but they were very apt to manifest themselves during the menstrual period. This was especially true if the organs were covered by exudations; in organic ovarian disease the only cure was removal. He mentioned one case of nervous disorder of eight years' duration, treated some time by an alienist, cured by ovariotomy. In other like cases he had removed the ovaries with good results. But in definite forms of brain disease he had not seen special benefit from removal of the ovaries. Unless physical signs of disease of the ovaries were present, he would not advise their removal for epilepsy. His experience with ovariotomy for epilepsy had not been very favorable.

Dr. Benjamin Sachs thought from Dr. Wylie's remarks that there was to be little room for controversy between the neurologists and gynecologists. He did not believe that any present would be in favor of subjecting the ovaries to any severe treatment for chronic constitutional neuroses, such as epilepsy and chorea. He knew of two

cases in which the ovaries were removed for the cure of epilepsy. In one, the attacks ceased for four months, and in the other, about nine months, and then returned. It was but natural that they should return. One of these cases showed that hystero-epilepsy might exist with perfectly normal ovaries, and that the neurosis might continue after removal of those organs. He thought the subject would reduce itself to the question, Should the ovaries be removed for hystero-epilepsy? If the gynecologist found actual changes in those organs, their removal might be justifiable, but in a large number of cases of hysteria which came to the neurologist the ovaries showed no actual changes. The hyperæsthetic ovary was only a part of a general hyperæsthetic constitution. If it were removed, the hyperæsthetic state would probably break out in some other place. It seemed to be only a question of whether the symptoms would return within six months or within a year.

Dr. Putnam-Jacobi first spoke of the necessity of distinguishing between those cases in which the pain was in the ovary and due to some ovarian disease, and those in which it was only an hallucination of the hysteric brain. In grave hysteria, or constitutional hysteria, in which the symptoms developed without apparent cause, the patients were usually remarkably free from organic, uterine, or ovarian disease. In those cases the question of whether removal of the ovaries would have any effect upon the hysteria or nervous disorder would depend, she thought, upon whether the operation would have any effect upon the brain. She thought ovaritis never occurred as a primary disease, any more than did engorgement of the lymphatic ganglia. She believed it invariably began in an endometritis at the fundus, and on this account it was exceedingly difficult to distinguish between symptoms properly belonging to the ovary and those arising from the endometritis. Nausea and tympanites were two symptoms markedly characteristic of lesion of the utero-ovarian nerve, if she might so speak. Latest observations, she believed, showed that although the ovaries received nerves from the lumbar plexus and sympathetic, yet all the filaments terminated in the blood-vessels, so that the first effect of any irritation of the ovarian nerves was relaxation of the blood-vessels, and the remote effects consisted primarily in vaso-motor disturbance. Angel had shown that one of the fundamental difficulties in certain forms of neurasthenia was a cramp of the blood-vessels of the brain, causing a special form of cerebral anæmia. Of the remote disorders from ovarian trouble there was one which had not received sufficient attention, except in England. It was so-called ovarian dyspepsia, which might be interpreted as a cramp of the blood-vessels of the mucosa of the stomach. She had relieved one such case by the galvanic current.

Dr. W. R. Birdsall thought the conclusions of Dr. Wylie, regarding operations in these cases, were reasonable; that an operation should not be undertaken unless there were some other evidence of ovarian disease than the nervous disorder. Dr. Wylie's experience with removal of the ovaries in such cases, when they showed no local signs of disease, would probably prove that of future operators. His own experience with this class of patients was such as to lead him to think that removal of symptoms in one direction would frequently be followed by an outbreak in another direction. He mentioned one case in which treatment of the ovarian and uterine condition corrected what appeared to be reflex nervous disorder; while in three cases removal of painful ovaries had not resulted in curing the pain. In other affections, as well as in ovarian disease, removal of the diseased organ, which had led to changes in the central nervous system, might not be followed immediately, at least, by cure of the painful symptoms. He thought there were two extremes to the question. There were cases in which the ovaries had been removed when they should have been let alone, while in others their removal would have been followed by cure.

Dr. H. T. Hanks, taking a practical rather than a physiological or theoretical stand-point, viewed the subject about as had Dr. Wylie. There were many different conditions which would cause pain in the region of the ovary, and in some, judicious and persistent treatment of different kinds, including electricity, would give relief. When, in connection with the symptoms referred to the ovaries, physical signs of disease were evident, they should be removed.

Dr. H. J. Boldt said he took about the same ground as the other speakers. Dr. Wylie, he thought, was very fortunate in relieving a patient immediately of her symptoms by removal of the apparently healthy ovaries, when the patient had been bedridden for so long a time. He had a similar case in which improvement took place after the operation, but in the course of time the old symptoms returned. Also in a case of hystero-epilepsy growing worse with advance in age, attacks brought on by pressure on the ovaries, failure to obtain relief by other means, removal of the ovaries caused improvement for a time, but the attacks gradually returned. He believed there was one other case with a similar history on his books. Therefore he had made up his mind that, where the ovaries were apparently normal, their removal would not cure the reflex nervous condition, of whatever nature it might be. Operative treatment in such cases was sometimes followed by a worse condition of the nervous system than had existed previously. He had cured one case of vaso-motor disturbance, manifesting itself in swelling and discoloration of an upper extremity, by treating pelvic disease with the tampon, etc.

Dr. Goelet had cured attacks of epilepsy, preceding and following menstruation, by dilating the cervix. He had seen a case of reflex irritation in the spine, diagnosticated and treated for spinal meningitis without success by a distinguished neurologist, which he afterward found to be due to ovaritis and salpingitis caused by anteflexion and stenosis of the uterus, completely cured by cervical dilatation.

Dr. Field thought an interesting question was, How many patients who had lost their ovaries were then in an asylum for lunatics? About five years ago he was somewhat alarmed at the number that it seemed might enter Blackwell's Island. The past year, however, there had been only five. If it was the custom among gynecologists, as Dr. Wylie said it was with him, to have patients examined by an alienist before removal of the ovaries, it would seem that the operation must have had something to do with precipitating the insanity. He had no doubt that many of those patients were predisposed to insanity, but the effect of the operation, including shock and etherization, must have had something to do with bringing on the insane state. Probably thirty or forty cases of this kind had come under his observation at Blackwell's Island.

The Chairman remarked that if a physician took up a specialty he would certainly relieve certain disorders pertaining to that specialty, and by his treatment also relieve certain functional disorders; and the enthusiasm of the patient was likely to lead him to expect much from the same treatment in similar cases. Thus the specialist, unless his mind was broad, was in danger of falling into vagaries. If one relieved epilepsy by an operation upon the pelvic organs, it was very necessary, if he would not fall into erroneous conclusions, to know what epilepsy would do if left alone. In 1828 Esquirol put his insane epileptics on all the various forms of treatment then in vogue, subjecting some to one, and others to another, form of treatment, while some were let alone, and he got equally good results in the several classes. All improved for a time, and all relapsed for a time.

If one had a disorder of the conscious nervous system, as a sciatica, he could locate it exactly; but it was a peculiarity of a disorder of the involuntary nervous system that one could no longer exactly locate it. All those disturbances arising in half-consciousness were much more painful

or distressful to the patient than those arising in consciousness. The involuntary nervous system had greatly more to do than merely contract and dilate the blood-vessels. It presided over all the organic functions of the body, and any disorders of it were only half-conscious, and proved very distressing. Because only half-conscious, it was very difficult to localize reflex disturbances. While he was very sceptical with regard to the value of ovariotomy in epilepsy, yet he had seen two cases in which epilepsy ceased with the cure of a vaginitis. The cases of ovarian epilepsy which had come under his observation were not of grand mal, but of slight loss of consciousness.

Dr. Wylie did not know that any of his cases of ovariotomy had landed on Blackwell's Island. He hoped Dr. Field would publish those cases referred to, of insanity following removal of the ovaries, together with the names of the operators.

Dr. Field said he did not know that it was proper to mention the names of the operators, but, since Dr. Wylie had requested it, he would state that of the five cases which had come to the asylum the past year one had been operated upon by Dr. Wylie; one by Dr. Lusk (although rather against his own advice); one he had already mentioned as having been operated upon twice, and left in a worse condition of insanity than before; one was operated upon in England; in the other case he did not recall the name of the operator. It would be difficult to get at the history of the thirty or forty cases prior to that time, and he thought really the less said about them the better; the reaction seemed to be taking place, anyway.

Dr. Dana was glad to hear such unanimity of opinion expressed by those present. It was not what he had expected after a perusal of gynecological literature.

OHIO STATE MEDICAL SOCIETY.

Forty-fourth Annual Session, held at Youngstown, May 22, 23, and 24, 1889.

An address was made by Dr. John McCurdy, President of the Committee of Arrangements, welcoming the Society to Youngstown. Secretary Collamore's report showed a membership of 576, and a decrease of eleven county societies in the State. A report on legislation for the protection of physicians from malpractice suits was made by Dr. Connor, of Cincinnati, and referred to a committee. On recommendation of the Finance Committee the dues were made $2, and the salaries of the Secretary and Treasurer were increased from $75 to $125 per annum.

Election of officers resulted as follows: *President*—Dr. John McCurdy, of Youngstown; *First Vice-President*—Dr. W. J. Conkling, of Dayton; *Second Vice-President*—Dr. A. W. Ridenour, of Massillon; *Third Vice-President*—Dr. C. W. Tangeman, of Cincinnati; *Fourth Vice-President*—Dr. J. E. Woodbridge, of Youngstown; *Secretary*—Dr. G. A. Collamore, of Toledo; *Assistant Secretary*—Dr. E. C. Brush, of Zanesville; *Treasurer and Librarian*—Dr. T. W. Jones, of Columbus. Columbus was chosen as the next place of meeting, the first Wednesday in June, 1890.

Dr. Orpheus Evarts, of College Hill, O., read a paper on "The Natural and the Supernatural in Medicine." Dr. Henry S. Upson, of Cleveland, read a paper on "Localization in Diseases of the Spinal Cord." Dr. Rufus B. Hall, of Cincinnati, read a paper on "Abdominal Section for Inflammatory Diseases." Dr. J. A. Battles, of Youngstown, read a poem entitled "The Physician and Surgeon," and was asked to write another for next year. A few observations on the "Etiology, Prognosis, and Cure of Incipient Cataract, without Operative Interference," was the subject of a paper by Dr. A. R. Baker, of Cleveland. "Injuries to the Head," was the title of a paper by Dr. G. M. Allen, of Cleveland. "Pressure as a Remedial Agent," was the subject of a paper by Dr. John McCurdy, of Youngstown. "Intestino-vaginal Fistula," was the subject of a paper by Dr. R. A. Vance, of Cleveland; and "Trephining," by Dr. George Goodhue, of Dayton. "Modern Theories of Tubercle and Therapeutic Tests," was the subject of a paper by Dr. H. J. Herrick, of Cleveland.

Dr. A. B. Thrasher, of Cincinnati, read a paper entitled

LARYNGEAL PHTHISIS.

He said it is established beyond a reasonable doubt that at times this is a primary affection. While the rule remains that the lungs are generally affected either with or before the larynx, yet Demme's case has disproved the statistics of Heinze, as tubercular disease of the larynx was found in death from tubercular meningitis. The special reason for invasion of the larynx was thought to be due to a weakened condition of the organ from abuse of the voice, either by improper method, over-use, or by using the voice in a bad atmosphere. The theory of specific infection by the Koch bacillus would scarcely hold good, as if the bacilli were inhaled the nasal mucous membrane should be more frequently affected. If it were exhaled from the lungs or carried out in the sputa, the surface of the mucosa would be first affected, while, as a matter of fact, the tubercular disease first began below the surface.

In uncomplicated cases Dr. Thrasher thought the laryngoscopic examination would establish the diagnosis. Small multiple ulcers, with ragged edges, on the undersurface of the epiglottis, the edges of the vocal bands or over the ary-epiglottic folds, on a pale, œdematous surface would mean tubercle. Pale thickening of the free edge of the vocal band or of the tissue over the arytenoids, this latter assuming a pyriform shape, implies tubercle. In syphilis the ulceration is on the buccal surface of the epiglottis—one large ulcer, surrounded by highly inflamed tissue, with involvement of cervical glands; in cancer, one ulcer on the apex of a tumor, usually on the ventricular band, preferably the left one, with marked redness of larynx and pharynx.

The general treatment does not differ from that of phthisis pulmonum—locally, lactic, chromic, or acetic acid to the ulcers, or, preferably, the galvano-cautery; cocaine, menthol, morphia, by spraying solution in vaseline during inhalations. By these means the patient is able to take food and is free from much excruciating pain which accompanies the last stages.

Dr. Max Thorner, of Cincinnati, read a paper entitled

CHRONIC THROAT AFFECTIONS OF RHEUMATIC ORIGIN.

Chronic painful affections of the throat, pharyngitic as well as laryngitic, are sometimes due to rheumatism. These cases are usually very obstinate and resist every treatment except that which is directed against the diathesis. The symptoms are pain in or about the throat; in pharyngeal affections the pain is mostly located in the regions of the fauces and tonsils, and sometimes as far down as the hyoid bone. If the larynx is concerned, there is localized pain in and around the larynx; the whole region about the larynx and the upper part of the trachea may be painful to pressure; some tender spots are always present. The pain is intermittent, and patients suffer more during changeable weather. Locally there is more or less congestion, which is sometimes circumscribed and limited to small tender spots. In rare cases congestion may be absent. Neither ulceration nor swelling is found in the throat. The general health of the patients remains undisturbed, unless they suffer at the same time from other manifestations of rheumatism.

The diagnosis must be based on the history of the patient. Sometimes rheumatic sore-throat is found in people who have never suffered from rheumatism, but in the majority of cases this disease can be traced among their former ailments. The treatment for this affection must be chiefly that for rheumatism in general: local applications may assist in the treatment, but can never alone

effect a cure. Salicylate of soda, salol, oil of wintergreen, phytolacca, and iodide of potassium are of special value. Sometimes hot applications, and the faradic or galvanic current, are very effective in producing relief. One case, a lady of pronounced rheumatic diathesis, was not amenable to treatment until she had spent several weeks at the Hot Springs in Mount Clemens, Mich., whence she returned cured. Chronic rheumatic affections of the throat are found more frequently in men than women. Relapses are common.

Dr. J. C. Reeve, of Dayton, presented a paper entitled

THE EARLY DIAGNOSIS OF EXTRA-UTERINE PREGNANCY.

It was based upon a careful study and annotation of the symptoms present in a large number of reported cases, and was prepared with the object of directing the attention of general practitioners, into whose hands the majority of these cases fall, in order that relief may be afforded in time. The symptoms were individually considered and classified as: 1, Suggestive; 2, presumptive; 3, certain. By attentive study of these a diagnosis could generally be made, although in some cases the difficulties were insuperable.

The subject of treatment was only considered to show how the advocacy of different methods had led to undue depreciation of the possibilities of a diagnosis at an early period.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from June 9 to June 15, 1889.

Hartsuff, Albert, Major and Surgeon. Relieved from duty at Fort Hamilton, N. Y., and ordered to Fort Omaha, Neb. Par 9, S. O. 136, A. G. O., Washington, D. C., June 13, 1889.

Brown, J. M., Major and Surgeon. Relieved from duty at Fort Omaha, Neb., and ordered to Fort Meade, Dak. Par 9, S. O. 136, A. G. O., Washington, D. C., June 13, 1889.

Shannon, W. C., Captain and Assistant Surgeon. Relieved from Fort Meade, Dak., and ordered to Fort Yates, Dak. Par 9, S. O. 136, A. G. O., Washington, D. C., June 13, 1889.

Ives, Francis J., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort D. A. Russell, Wyo., and ordered to Fort Lyon, Col. Par 9, S. O. 136, A. G. O., Washington, D. C., June 13, 1889.

Philips, J. L., Captain and Assistant Surgeon. Relieved from duty at Fort Lyon, Col., and ordered to Fort Crawford, Col. Par 9, S. O. 136, A. G. O., Washington, D. C., June 13, 1889.

McCaw, Walter D., First Lieutentant and Assistant Surgeon. Relieved from duty at Fort Crawford, Col., and ordered to Fort McPherson, Atlanta, Ga. Par 9, S. O. 136, A. G. O., Washington, D. C., June 13, 1889.

Gibson, Robert J., Captain and Assistant Surgeon (Fort Trumbull, Conn.). Designated as medical officer for the encampment at Fisher's Island, N. Y., and to proceed to Fisher's Island, N. Y., August 1, 1889, and report to the commanding officer for duty at that post. Par 5, S. O. 133, Headquarters Division of the Atlantic, June 13, 1889.

Gandy, Charles M., Captain and Assistant Surgeon. Upon the abandonment of the post of Fort Concho, Tex., will report in person to the commanding officer, Fort Clark, Tex., for duty at that station, to relieve First Lieutenant Ogden Rafferty, Assistant Surgeon, reporting also by letter to the Commanding General, Department of Texas. Par. 7, S. O. 133, A. G. O., Washington, June 10, 1889.

Rafferty, Ogden, Lieutenant and Assistant Surgeon. On being relieved by Captain Gandy, will report for duty to the commanding officer, San Antonio, Tex., reporting also by letter to the Commanding General, Department of Texas. Par 7, S. O. 133, A. G. O., Washington, June 10, 1889.

Wales, Philip G., First Lieutenant and Assistant Surgeon (recently appointed). By direction of the acting Secretary of War, will proceed from this city to the Presidio of San Francisco, Cal., and report for duty to the commanding officer of that post, reporting also by letter to the Commanding General, Division of the Pacific and Department of California. Par 3, S. O. 132, A. G. O., June 8, 1889.

Official List of Changes in the Meaical Corps of the United States Navy for the week ending June 15, 1889.

Morton, O. D., Assistant Surgeon. Ordered to the Naval Hospital, Chelsea, Mass.

Hall, J. H., Passed Assistant Surgeon. Detached from the Naval Hospital, Washington, D. C., and granted six months leave to go abroad.

Lewis, D. O., Passed Assistant Surgeon. Detached from the Naval Academy and to Hospital, Washington, D. C.

Bright, George A., Surgeon. Detached from the Navy Yard, Norfolk, Va., and wait orders.

Marmion, R. A., Surgeon. Detached from the Receiving-ship Franklin, and to Navy Yard, Norfolk.

Bertolette, D. M., Surgeon. Ordered to the Receiving-ship Franklin.

Kidder, B. H., Medical Inspector. Ordered to the Naval Academy, Annapolis, Md.

Walton, T. C., Medical Inspector. Detached from the Naval Academy, and to the U. S. S. Chicago.

Beyer, H. G, Passed Assistant Surgeon. Ordered to the Training-ship Portsmouth.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending June 15, 1889:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	16	4
Scarlet fever	129	26
Cerebro-spinal meningitis	8	6
Measles	98	8
Diphtheria	132	50
Small-pox	1	0
Yellow fever	0	0
Cholera	0	0

Soluble Phosphate of Iron (*Journal de Médecine de Paris*).—Jolly has published an article showing that iron only exists in the blood under the form of phosphate. The following are his conclusions: The success of treatment by iron, other than phosphated, is subordinate to the richness of the organism in circulating alkaline phosphates; but as no indications can instruct the physician as to the amount of phosphatic alkali in his patient, he can only count upon the benefit of ordinary ferruginous medication. In such case, is it not reasonable to prefer a phosphated preparation of iron? M. Ch. Lecerf takes the same view as M. Jolly; and three years ago, at the request of Dr. Viry, he undertook the discovery of a soluble preparation of iron, of constant composition, and capable of being easily assimilated. It is known that the phosphates of iron are insoluble; they are only absorbed

through the intervention of the acids of the stomach, which are thus diverted from their special functions to promote the transformation and digestion of food. These conditions of decomposition are not peculiar to the phosphates; they exist for all insoluble preparations of iron, and their prolonged use nearly always induces digestive difficulties. The salts of iron which least affect digestion are those which are soluble in acids of organic origin; but these preparations are only rendered soluble by the decomposition of oxide or of pyrophosphate of iron in the tartrates or citrates of ammonia or potash. These oxides or phosphates of iron are dissolved in a moist state immediately they are precipitated; the solutions thus obtained are dried on glass plates, and supply the flakes which are usually found in commerce. This brief glance at the mode of preparing these iron compounds shows how difficult it is, if not impossible, to obtain products of a stable composition. It became, therefore, desirable to find a ferruginous preparation which should possess always identical properties. In Dr. Lecerf's researches he only studied the phosphates, being convinced of their value in anæmia, and of their superiority over all other salts, provided that it was not necessary to borrow materials for their solution from the organism. He found that there exists a combination of iron with citric acid which is very soluble in water, the solution having a neutral reaction on litmus-paper. This ferruginous citro-phosphate crystallizes in very small crystals belonging to the fourth system, and assumes a rhomboid or hexagonal form. They are slightly raised tablets or lozenges, or in which the angles terminating the longer axis are more or less truncated. This salt, the composition of which does not vary, owing to its crystalline form, offers as a phosphate a peculiarity which may be usefully noted, for it is a rare exception. Generally the ammoniacal citrate is used as a solvent for salts of iron, and all soluble phosphates may be dissolved in this agent. The salt described, although soluble in water, is very slightly so in the citrate of ammonia, and, if solution is effected by heat, is precipitated when cold. Dr. Lecerf believes that this new salt will prove serviceable in cases where iron is indicated. He adds that this salt, which he has taken himself and prescribed for many others, does not produce constipation.—*The Provincial Medical Journal*, May 1, 1889.

Syphilitic Fever.—Professor Fournier presented a patient at his clinic recently who illustrated one of the rare forms of syphilitic fever which has received the name of typhose syphilitique, so closely does it resemble typhoid fever. Syphilitic fever, although so long denied, is nevertheless very frequent, especially in women. The author has observed it in no less than one-third of the cases at the Lourcine Hospital. Symptomatic fever is not very common, for most lesions appear without febrile movement. However, an eruptive fever of invasion may appear with the roseola or papular syphilide. Essential fever is much more frequent, and presents two features important to know. First, it belongs to the secondary period, and especially to the first months of this period; and, secondly, it is much more common in women. The varieties of this fever are numerous, and marked types exist, such as the intermittent, irregular, and continuous. The intermittent is one of the most common types. The initial stage is often absent as well as the sweating stage. Only simple shiverings are noted, followed by a stage of heat and a terminal stage of moisture. It ordinarily occurs at evening or in the night, and the spleen is not affected. The intermittent form passes away the most quickly, but may last as long as three months. It is the form which gives way most readily to mercurial treatment, while quinine has no influence upon it. The continued form is, perhaps, more important because of the errors of diagnosis which it is likely to cause. The temperature is usually moderate, but in some cases may reach or exceed 104° F. The duration may be only a few days, but it may also last for several weeks, or even fifty days. Thus in these cases, contrary to the current opinion, syphilis may become a pyrexial disease. In syphilitic fever digestive troubles are very slightly marked, while in simple continued fever they are the predominant symptoms; besides, the tongue has a peculiar aspect and the fever does not last over a week. Between this and typhoid fever the diagnosis is still more important. The differential signs are mostly negative; there is absence of epistaxis, and the character of the facies is simply adynamic without stupor. There is absence of tympanitic enlargement of the abdomen, gurgling in the iliac fossa, diarrhœa, sibilant râles in the chest, enlargement of the spleen (except in rare instances), and the characteristic spots appearing on the seventh or eighth day. A peculiar phenomenon occasionally observed in syphilitic fever is that of boulimia coincident with the fever. Prognosis in the prolonged form of fever has a certain importance, for it leads to denutrition, anæmia, and a general atony from which it is difficult to relieve the patient. As regards treatment, mercurial ointment is advised in doses of four grammes at each friction for an adult. This quantity can be increased after a few days to six or eight grammes, but this quantity must not be exceeded unless in very grave cases or where the treatment is being carried out at a sulphur-water cure. Sulphur-water favors the tolerance of mercury without our being able to say just why. Doyon has been enabled under these circumstances to use a daily quantity of twenty grammes of the ointment without causing salivation. Vigorous friction for almost a quarter of an hour, preferably at night, is required for the smaller quantity and a longer time for the larger dose. The region is then covered with a layer of cotton and adhesive straps and the ointment is left upon the skin eight or ten hours. Two starch baths a week are given. Professor Fournier condemns the practice of neglecting treatment in suspected syphilis in infants as long as they appear healthy. He believes that if the father alone is syphilitic, treatment is not indicated, for heredity under these circumstances is rare. If the mother has syphilis of long standing and has shown no signs during pregnancy, then, too, treatment may be omitted. If, however, the mother has recent syphilis, and especially if she has shown signs of it during her pregnancy, we must not hesitate to treat the child, even if it appears perfectly healthy. It is sure to become syphilitic, and should be treated energetically from birth.—*Journal of Cutaneous and Genito-urinary Diseases.*

Arsenical Pigmentation of the Skin.—Dr. W. L. Worcester, of Little Rock, Ark., writes: "Cases similar to the one exhibited by Dr. Leszynsky at the meeting of the New York Academy of Medicine, February 19, 1889, have been reported by Jonathan Hutchinson, I think, within the past two or three years. I am unable now to give the reference. I have had two cases of the kind in my practice at the Michigan Asylum for the Insane. One was a case of pernicious anæmia, which recovered under the use of Fowler's solution, and which is reported in the New York *Medical Journal*, May 5, 1888. In the other case the drug was administered for enlargement of lymphatic glands, giving rise to suspicion of Hodgkin's disease. In both cases there was deep pigmentation, which disappeared in a short time after the suspension of the arsenic. Such, I venture to predict, will be the result in Dr. Leszynsky's case."

A Prize for Cleanliness.—A winter resident at Green Cove Springs, Fla., has offered a premium of $1,000 for the city or town in Florida which, on July 1, 1889, shall present the most cleanly condition in public and private premises.

Overcrowding of the Profession.—A Western physician recently read a paper before a medical society, in which he argued that all that was necessary to prevent overcrowding of the medical profession was to adopt Henry George's land-tax theories.

American Medical Association.

FORTIETH ANNUAL MEETING,

Held at Newport, R. I., June 25, 26, 27, 28, 1889.

FIRST DAY, TUESDAY, JUNE 25TH—GENERAL SESSION.

THE meeting was called to order by DR. HORATIO R. STORER, Chairman of the Committee of Arrangements. REV. THATCHER THAYER, D.D., the senior clergyman of Newport, offered prayer.

HON. HERBERT W. LADD, of Providence, Governor of Rhode Island, delivered

AN ADDRESS OF WELCOME

to the Association from the people of the State. He stated that not often were doctors' visits greeted with a smile, but the present occasion was a pleasant exception to this rule. Rhode Island is proverbial for its hospitality, which the members would shortly experience. In conclusion, the Governor hoped that all would take away pleasant memories of Newport.

HON. JAMES H. ELDREDGE, M.D., of East Greenwich, ex-President of the Rhode Island Medical Society, and one of the oldest members of the American Medical Association in the State, gave a cordial welcome from the profession of Rhode Island.

PRESIDENT W. W. DAWSON, of Cincinnati, next delivered the

ANNUAL ADDRESS.

The late Premier, Mr. Gladstone, after quoting the statistician who estimates the English-speaking people at the close of the next century at one thousand millions, says, "What a prospect is that of many millions of people, certainly among the most manful and energetic in the world, occupying one great continent." This destiny in numbers is startling, but the assertion of Dr. Dollinger, a German scholar, portrays the culture of the future almost as strikingly when he says "that the intellectual primacy of the whole world is certain to fall to the Anglo-Saxon race." Most of that race will be in America.

Looking to such a future the position of the learned professions is certainly conspicuous—their obligations imperious. Medical men should be loyal to this grand destiny.

An eminent modern critic, in discussing civilization in America, while admitting that we have well solved the political and social problems, asks what have we done to solve the human problem, "the humanization of man in society." The struggle in his own country, he asserts, has resulted in "an upper class materialized, a middle class vulgarized, a lower class brutalized."

We trust that our efforts have yielded better fruit; and since medical science and medical men are prominent factors in society, among every people, we may well ask, what they have accomplished, what part they have here taken in the solution of the vital problem? In the "Century of Medicine," Professor E. W. Clark in his classical address says:

"It is not an extravagant assertion to say, that in all this turmoil, change, and progress (referring to the revolutions and changes in society, religion, and governments for the past century), medicine has kept abreast of the other natural sciences, of politics, and of theology, and has made equal conquest over authority, error, and tradition," and it may be added, has contributed largely to man's comfort, happiness, and advancement. To intensify this, reference need only be made to some of our triumphs, to vaccination, to anæsthesia, to sanitation, the prevention of pestilence, the lengthening of human life. It is, however, more especially the contributions of the profession in America to which attention is desired at this time. What are we doing in the humanization of man, in the work of civilization?

Are our medical practitioners and our medical teachers what they should be? We shall see. Criticisms abound concerning the defects of medical education. Those who do not condemn, often ridicule; these criticisms and strictures are made for the most part, it must be said, by gentlemen unacquainted with teaching, without any practical knowledge of the constitution of medical colleges, or of the toil, devotion, and sacrifice made necessary by those engaged in didactic and clinical instruction.

These censorious addresses are delivered before and to a body of professional gentlemen, the peers of any, some of whom have grown gray in the hard service, others are still in the prime of life, with reputations co-extensive with civilization. The rest are young, full of life and enthusiasm, fired with ambition to render loyal service to that profession which they have chosen. Can our system be so defective? The pessimistic orator seems to forget that he is the product of the system of medical education which he is so severely condemning. Some one has said, "By retrospection and introspection an individual, like a profession, may be benefited." In this self-examination we should have but one motive, the elimination of error, the development and support of truth.

Education cannot make all great or equal. It tends, however, to make all safe. In the crucible of private, practical life, evolution asserts itself and the fittest survive.

In making a retrospect of our profession it may be well to look for a moment at medical teaching in this country.

The way is long between Aristotle and Bichat, and Buckle says that he found no middle-man in this long period; it is darker than it is long. During all this time medicine was not taught legitimately. The renaissance, if it may be so called, began with Hunter and Bichat. No real progress, however, could be made while oxygen remained locked in the silent embrace of all organic and inorganic nature. Priestly, escaping from the religious and political contests, and it may be persecutions, of the old world, came to this country to demonstrate his great phlogiston, Oxygen.

Bichat and Hunter restored the proper study of medicine. They represent the turning-point from idealism, speculation, and theory to accurate and close observation. The latter, John Hunter, in 1767, was lecturing and taking students into his own house, and it is curious to know that here, in far off America, Shippen and his contemporaries in Philadelphia and New York, about the same time, or very soon after, began teaching medicine and surgery upon essentially the same plan. Of these men, one who so recently passed away that you can almost hear the sound of his voice and feel his magnetic presence, when speaking of the men who lived at the close of the last, and during the early part of this century, said, and justly said, "Not a few of them were the worthy

peers of Roux, Abernethy, Crampton, Bell, Graefe, and Scarpa."

To quote again:

"During the past century medicine has been enfranchised from superstition, *quasi*-charlatanism, bold empiricism, and speculation and has developed into a symmetrical science, affiliated with the other natural sciences, studied by the same methods and by the same appliances as they are, and like them has been planted upon the solid basis of fact and demonstration."

It may be profitable for us to inquire and determine what part the profession in America has taken in placing medicine upon the high ground which it occupies. What have we done, what are we doing, and what forecast can we make of the future?

At the close of the eighteenth century Boerhaave declared that all that had been learned up to that time was comprised in three propositions: "Keep the head cool, the feet warm, the bowels open." All other pages in the volume which he left were blanks. Many pages, however, it will not be denied, have been filled during the present century. What have been our contributions? Have they been such as to rank us with the acknowledged conservators of mankind?

In giving attention to this subject let us for a moment reflect upon the peculiar position of the profession and of medical teaching in this country. For many years (and even now), with few exceptions, medical colleges were the creation of the members of the profession, most often of the faculties composing the schools, without endowment —indeed, it may be said that almost everything on this continent is endowed, except medical colleges—without Governmental aid, depending for their support upon the sacrifice of time and money on the part of the gentlemen occupying the chairs. Yes, not only without patronage from the Government, but society, from some unknown cause, has ever been against legitimate medicine, depending upon the scientific physician in time of trouble, yet in the interim openly supporting all sorts of shams, frauds, and impostors.

Elsewhere, college work is provided for by the State; especially laboratory investigations—the nature and the genesis of disease. Hence it is not strange that in such departments we may not be so far advanced as our European brethren, but while they have been engaged in experimental studies we have developed the practical. Everywhere is seen among us an earnest, a burning desire for higher culture, for more exact and accurate knowledge. Especially is this true of our younger members and of those about entering the profession.

A movement is being made to concentrate those who have had preliminary advantages—those who enter the profession as college-bred. No objection can be urged to this if it be not too exclusive. All efforts, in fact, to refine our profession without emasculating it, should meet with judicious approval.

THE PHYSICIAN OF THE FUTURE.

Whence are medical students to come? What facilities are now afforded, and what does the future promise for the education of our young men, the class from which the medical student, the "coming doctor" is to be selected? The answer to this question will give some comfort, we trust, to the pessimist and soothe the restless and at times unreasonable critic. And now as to our resources for this work.

By the last census it was shown that nearly four thousand institutious—schools for higher learning—existed in the United States, and that nearly four hundred of them ranked as colleges and universities. In these are massed, yearly, nearly sixty thousand pupils. They, together with two hundred thousand common, or primary schools, in the higher grades of which the curriculum nears that of many colleges at home and abroad a third of a century ago, may be looked upon to supply, year after year, a better material from which medical students will be drafted.

Professor Charles W. Eliot, in his beautiful and forcible centennial response, enumerated our educational facilities more generously. He painted our future more hopefully when he spoke of the eight million children in elementary schools, two hundred and fifty thousand in secondary schools, sixty thousand in colleges, with three hundred and sixty thousand teachers to train and develop them.

Everyone travelling through the States—especially of the West and South, and those situated in the far away mountains, and on the Pacific—must be impressed with the onward march of public instruction, the gradually increasing general intelligence, and the vast sums that are annually expended for the education of the people. Public school buildings, by their size, adaptation, and attractive surroundings, give an impression which the most sceptical must feel, a promise of the future which cannot be misread. From such as these, scientific medicine must reap a share. Every teacher, everyone connected with the examination of candidates for the medical degree, knows—and the knowledge is reassuring—that year after year the grade of the medical student is advancing, that the material out of which the practitioner is made is constantly growing better, becoming stronger—in other words, that the preliminary education of our students is steadily becoming more broad and comprehensive. I gave utterance to this view a few years ago, in an address which I had the honor of delivering to the State Medical Society of Ohio. Time, I believe, has confirmed what I then said. This confirmation is seen in our graduates as they go forth to take up the line and battle of life. Are they not the equals of the graduates in other professions, in law and theology? As life advances, are they not the peers of any in all the useful elements of true manhood? Are they not the citizens of best rounded characters, citizens most relied upon by their neighbors in foul as well as fair weather?

Again, in addition to facilities already referred to, the most generous provisions are being made, all over our land, for institutions which will be worthy to be called universities. From these, graduates will emerge, worthy to rank by the side of those bearing the prized degrees from Oxford, Cambridge, Paris, Heidelberg, or Leipsic.

During the summer of 1888 I witnessed the beginning of a university in California, which in scope and equipment will surpass, probably, any school upon the continent. Should Governor Stanford live to develop his conceptions, that far-off State will have an institution of which not only the Pacific Coast, but our entire country, yes, all civilization, will feel justly proud. It may be so liberally endowed that it will command the best abilities of the world.

Of course, upon such an occasion as this it would hardly be expected that I should, in detail, refer to the many liberal donations and bequests which have been made by generous citizens for developing higher culture —more comprehensive education. I will, however, be pardoned for referring to a few, and I may say, without being too enthusiastic, that the future is aglow with promise. The high-hearted examples which have been set will be followed by other favorites of fortune, until this country may surpass the world, not only in common schools, but in her institutions for broader and deeper education.

In looking at this promising future may we not hope that before another half century closes students from the old world will flock to this, to sit at the feet of the wisdom here installed? Is it too much to hope that, in the not far-off future, the preliminary education of our students will be equal to that required in the best schools of the world?

Defective as has been much of the material, yet have we not produced some marked results? Our best are equal to the best anywhere; mediocrity always and everywhere finds its own. The poor in medicine, the weak brother, however much we may deplore him, however

much we may train him, we have, like the poor, always with us. This is the lot of humanity in all lands, among all peoples, new or old.

A word as to the physical qualities of "the coming doctor." Recently a distinguished foreign traveller, in speaking of our educational facilities and national peculiarities, said: "Students are much calmer than their colleagues in Europe. They don't at all trouble themselves about politics, or affairs outside their line of duty, and, with the practical sense which animates the nation, they try to make the best use of their time. They fight no duels, and it is only for health and recreation that they take part in various sports and games." These remarks apply with equal, in fact, with greater force, to medical students.

It is to the country schools, not the city-bred, that medicine must look for many of her strong recruits. Cities too often emasculate—young men are vitiated by indulgence and vice before they become possessed of serious thoughts, before they realize the elements of a healthy, vigorous life. It is this country-bred, this excellent material which is, as we have seen, yearly growing better and better qualified to enter upon the duties of the profession. From these we must look for the men of distinction, the leaders of the future.

Is this picture overdrawn? One word more. In many of the States of the Union, in addition to the liberally supported free schools and schools for higher education, already colleges have been established through the munificence of the General Government, in which the degrees of A.B. and A.M. may be obtained. They are absolutely free colleges, at which the poorest boy in the commonwealth may receive a classical education. And here, you will allow me to say, we can not insist too strongly upon the necessity of classical education; without it the medical man must ever be at a disadvantage. Without a knowledge of Latin and Greek sure and distinguished success is uncertain. The student may neglect algebra, and the higher mathematics, but let him, by all means, have a liberal knowledge of languages.

At the last commencement of one of our Western schools, "forty per cent. of the graduating class had been admitted on diplomas from literary or scientific colleges; the balance of the class had received from one to five years of academic or collegiate instruction." This college is without endowment—depending entirely upon the learning, devotion, and sacrifice of the Faculty.

But to return. Prominent among the States in providing institutions for advanced culture, the great frontier State, Texas, claims a high position. The University of Texas will be one of the most liberally endowed; millions of acres of land have been donated for university purposes. There, in that Empire State, may yet be seen one of the greatest schools of literature, science, and philosophy on the Western Continent. The University of Virginia, projected in the early days of the century, by her great commoner, Thomas Jefferson, has yearly sent forth graduates equal in all the elements of advanced scholarship to those from any school. This may seem high praise, but the records of her alumni justify me. The same may be said of Harvard, Yale, Princeton, Columbia, Cornell, and of most of our older institutions. The University of California has already an annual revenue of about two hundred thousand dollars. The Michigan University, with a yearly income of almost a quarter of a million of dollars, has well nigh two thousand students, taught by more than one hundred teachers.

Let us not, gentlemen, be impatient; the influences are already projected that will give us students equal to—up to—the highest standard of preliminary preparation. If we have accomplished so much in our primitive stage, what may we not expect when all our great preparatory works come fully into action?

From this view of the resources from which medical students are to be drawn, and of the liberal preparations and facilities for their culture, we may well ask, what is the profession doing to profit from such advantages?

Some of the classical schools at Oxford and Cambridge were organized as early as the thirteenth century, but the systematic, scientific study of medicine and surgery came long subsequently—not four hundred years later—about the middle of the eighteenth century. It was first projected in Great Britain, and soon after in our Atlantic cities. Unlike the Old World, our fathers had a wilderness to conquer before progress could be made. When the Pilgrim Fathers left England, reading and writing were rare accomplishments; chimneys in that country had just been invented, and flock beds were luxuries. The adventurers—the emigrants to these shores from that ancient and imperfect civilization—had much to learn, but in the midst of their pitiable ignorance, facing great hardships and pressing wants, they were quick to provide educational opportunities for all. The result of their efforts are apparent—they are before us. Could more have been accomplished in one century?

MEDICAL SCHOOLS.

Our medical colleges now number a few more than one hundred. They may be classed as: 1, Metropolitan, those in large cities; 2, medical colleges in less pretentious cities; 3, medical colleges in small cities; 4, State medical colleges. For convenience, however, we may speak of them as metropolitan and provincial.

Before speaking more definitely of our medical institutions allow me to refer for a moment to the proposition, that medical schools in our country have been developed by the labors, by the self-sacrifice of the profession. As previously stated, it may be said that in this country everything is endowed except medical colleges, schools for teaching medicine. Yes, all financial responsibilities have been and are assumed by the faculties, by men who give every hour not devoted to "earning the guinea" to college work, and, in most instances, without pecuniary reward. It is only recently that the wise, the generous, the favorites of fortune, and a few of the States have conceived the idea of endowing medical schools, institutions where medicine and surgery can be cultivated without the embarrassments of financial responsibility. In the presence of such facts the work of the grumbler seems indeed ungracious.

In our metropolitan colleges every physician may feel a just pride; their graduates, most of them, will compare favorably with those educated anywhere on this earth.

The accomplished Dr. Senn, after a liberal experience with foreign schools, said: "There is no question in my mind that the average American student learns more in one month than the average German student in three. He learns more, not because he has better teachers or better facilities, but he makes better use of his time. I am satisfied that in our last graduating class I had at least a dozen students who, after studying three years, would pass a brilliant examination in any English or German university. They would have felt at home even in a dress coat in Volkmann's clinic, passing their final examination."

Provincial schools do praiseworthy, yes, thorough work in training young men, not only in rudimentary branches, but in practical, clinical studies. Many supplement these by hospital attendance in the great cities and by post-graduate courses. It is gratifying to know that these organizations are being established in all of the great medical centres.

The advance in medical education is again most distinctly pronounced by a remark recently made by one of our distinguished fellows, an American-bred physician, of whose fame we are all justly proud. In a conversation, Dr. Battey said: "When I began to practice, thirty years ago, there was scarcely a graduate within fifty miles of my residence; now, however, there is hardly a practitioner in the same territory who is not a graduate, and, year after year, a portion of our young men leave home to avail themselves of clinical advantages, to attend post-graduate instruction."

Could anything show more forcibly the conservative and steady growth of medical culture?

HAVE MEDICAL COLLEGES INCREASED TOO RAPIDLY?

Should they be established in small cities where clinical material is limited, where it must be comparatively scarce? Before answering this it may be well to reflect upon the proposition, that in our own country, as well as elsewhere, great achievements have often been made in the provinces and not always under the shadows of the universities. One of the great operations waited for years for a metropolitan disciple—one to take it up—and that too, long after the provinces, at home and abroad, had demonstrated its vital utility, its claim upon the scientific and skilful surgeon.

As our population increased from three to sixty-five millions, the demands for medical men were great—colleges increased necessarily. Have they multiplied in undue proportion?

In answering this question, I beg again to quote from my beloved master, Samuel D. Gross, to whom this question had been put. After mature deliberation, he said: "Our colleges are not annually graduating one physician for each county in the States and Territories. This is certainly not exceeding the demand." A considerable proportion of those who graduate never enter the ranks—death and desertion claim a large share. It would simply be impossible for the metropolitan schools to graduate all required.

For the introduction of young gentlemen into the profession there is a mutual responsibility between teachers and preceptors. In very truth it may be said that colleges do their duty, their very best, with the students furnished by the preceptors. Give us liberally-educated young gentlemen and we will furnish graduates worthy of the degree. Medical colleges, however, do not make the physician. They merely furnish the foundation work; the individual must do the balance. In no place is evolution so marked—the fittest will and should survive.

LABORATORY WORK.

Huxley says: "The microscope extends the realm of pathological anatomy to the limits of the invisible world."

"The intimate alliance between morphology and medicine has made the natural history of disease attain a remarkable degree of perfection."

Dr. George M. Sternberg, the distinguished pathologist, recently connected with the Smithsonian Institute, in referring to some of the laboratories established in this country for the study of pathogenic micro-organisms, says: "It is no longer necessary to go abroad for instruction in this department of science, since the laboratory of Professor Welsh, in Baltimore, and the Hoagland Laboratory, in Brooklyn, afford facilities which are unsurpassed by any of the laboratories of the old world."

Indeed, it may be said that provisions for the study of pathogenic micro-organisms are established in most of the leading schools of this country—in New York, Philadelphia, Boston, Baltimore, and the cities of the West and South.

You will pardon me for mentioning some of the investigators.

Johns Hopkins University has for its director, Professor William Welch. The Hoagland Laboratory, of Brooklyn, N. Y., established through the generosity of Dr. C. N. Hoagland, has been built and equipped in the most complete manner for research work in bacteriology and experimental pathology. Professor George M. Sternberg is to be the director of this advanced institution.

At the University of South Carolina, Dr. Meade Bolton, who has had the best of training at Berlin and Göttingen, is at the head of a laboratory. Dr. H. C. Ernst has the direction of a bacteriological laboratory in connection with Harvard School of Medicine.

Professor James T. Whitaker, who had the honor of being the first American student of Robert Koch, demonstrated, at Cincinnati, in 1882, the tubercle bacillus, after a lecture upon the subject before the Philadelphia Academy of Medicine. In 1887 the Medical College of Ohio imported a complete outfit for bacteriologic study. The conductors of the laboratory, Drs. Rachford, Cameron, and Freeman, during the first course, had the opportunity of doing some good work in the discovery of the typhoid bacilli in the reservoir supplied from the Ohio River, then at a very low stage. This discovery led to the general adoption in the city, as advised by leading physicians, of boiling all drinking-water, a plan which undoubtedly limited the spread of the disease.

Among others may be mentioned Dr. Prudden, of the College of Physicians and Surgeons, of New York; Dr. Geo. A. Kemp, of Brooklyn; Dr. Mall, of Baltimore; Dr. Booker, of the same city; and Dr. Frank S. Billings, of Lincoln, Neb.

One of the earliest, most accomplished, and accurate cultivators of micro-organisms is Dr. James E. Reeves, of Chattanooga. His technique is singularly beautiful. Many of his preparations are to be found in the National Museum.

Dr. Victor C. Vaughan and Dr. Heneage Gibbs conduct laboratory work at Ann Arbor.

The University of Pennsylvania has at the head of its laboratory Dr. John Guiteras, a pathologist who has distinguished himself in the study of the origin and spread of yellow fever.

Thus it will be seen that in all parts of our country—East, West, North, and South—laboratories are being established for original work.

HISTORY OF MEDICAL TEACHING IN THIS COUNTRY.

A brief review of medical teaching in this country will be pardoned—it may be profitable—it will certainly illume the present, and may be somewhat of interest to the future.

The first medical lectures were delivered by Dr. John Morgan and William Shippen, in 1767, in Philadelphia. Dr. Rush and Dr. Physic soon after participated, and in 1768 the medical department of the University of Pennsylvania was organized, that great school which is steadily advancing to the highest station. Philadelphia was a small, a provincial city at that time; now she is only second to the great metropolis in numerical strength, but second to none in the thorough equipment of her medical schools.

Contemporaneous with Philadelphia, an organization was projected for medical instruction in New York. In 1767 the first steps were taken which resulted in the school ever since known as the College of Physicians and Surgeons, one which challenges the confidence of all. The medical colleges of New York, endowed, not by Government, but by her public spirited citizens, have won the honors which they wear so well.

In 1785 the first school was organized in Boston. The chairs were four, and the session four months. Harvard is the outgrowth of this humble beginning of that provincial faculty.

In 1800 the first medical instruction was given in Baltimore; since then the schools of Maryland have occupied a deservedly high position. Recently one of her citizens made an endowment by which the Johns Hopkins University will be equipped for the most thorough work, experimental work, laboratory studies, a range and grade of investigations *en rapport* with the spirit of the times.

This great benefactor has also given to Baltimore one of the most completely equipped hospitals to be found on this earth.

The great Mississippi Valley was yet unknown, but soon after the close of the Revolution emigration began, and, as early as 1799, Dr. Samuel Brown organized the medical department of Transylvania University. Dr. Benjamin Dudley effected a reorganization in 1819. This school, after many prosperous years, having graduated men who acquired distinction at home and abroad, was transferred,

or rather most of the faculty removed, to Louisville, when and where the University of Louisville was founded.

During the early part of the century, medical schools were organized in several of the Eastern States, usually under State or Church patronage. Most of them exist to-day. Some of the most distinguished men in our profession have been associated with these institutions.

As the West and South were peopled, medical schools were established in cities and promising towns. As early as 1819, Dr. Daniel Drake secured the charter of the Medical College of Ohio, and had it legally connected with the City Hospital. The faculty constituted the hospital staff, the members of which were required to give clinical lectures—the first forward step on the continent in blending didactic with clinical instruction.

The physicians in South Carolina began medical teaching in 1823, and those of Louisiana in 1835. In both of these States schools of high character have been maintained.

In closing this very brief review of our colleges, metropolitan and provincial, I think it may be said that year after year the standard of the doctorate is being elevated, preliminary examinations and graded courses are being adopted; the smaller schools—to which most blame is attached, whether justly or not—with a disregard of self-interest seldom seen, are yearly reducing the size of their classes by insisting upon higher preliminary education, by extending the curriculum, and by graded instruction.

MEDICAL JOURNALS.

Medical journals, metropolitan and provincial, are the heralds, the vanguard of medical progress, the exponents of professional culture. They are closely associated with the colleges in education and in post-graduate instruction. In them appear the best thoughts of the best men; they constitute the great forum of intellectual combat; upon their pages pretension is analyzed and estimated, and worth recognized; that which is new or original is endorsed, or rather encouraged; it is only the plan, the original investigation which is endorsed; the results, the conclusion must be subject to the crucible of test and trial.

The London *Lancet* and *The American Journal of the Medical Sciences* were almost contemporaries—who can over-estimate their value, their influence on medical progress. While our journals, both metropolitan and provincial, are freighted with the best thoughts of the best men, yet, it must be confessed, that trash and light material—very light material—may be found in all; but the reader, nevertheless, will find much that is not worthless.

The *Journal* of this Association has won its way to its present high position by its dignified course and its essential scientific character; but has it reached its full usefulness? A learned and distinguished author, and a highly-prized fellow of our Association, at my suggestion, gives his views upon this question.

Dr. Comegys says: "The undertaking, seven years ago, to establish a weekly journal, was a happy conception and has been carried on as successfully as the resources of the Association would admit. To Dr. N. S. Davis unstinted praise is due; proportionate praise is also due to the Board of Directors with whom he has been associated.

"A large number of the members believe that it is entirely feasible to enlareg the *Journal* and give to it increased capacity for usefulness; indeed, that it should be made more fully capable, as the organ of the Association, to assert and maintain the dignity and power of the medical profession as one of the greatest factors in civil life; that to it society must ultimately turn to find, not only the resource to assuage the distress arising from the diseases and accidents of life, but as to its protection from all those evils that fill the land with apprehension of desolation and ruin.

"We know to what an immense extent we can estop the approach of the pestilences that desolate lands and which menace, through the paths of commerce, the whole area of civilization. We know what we can do to improve the homes and places of labor of the lower and toiling classes of cities and other crowded centres of population. There is nothing, indeed, connected with our own social state, which the medical profession should not supervise, and which it should not have the power to control. A great organ is necessary to enlighten, strengthen, and lead the profession in all directions to bring to bear its beneficent agency for the correction of the terrible evils of society.

"Such a journal must be made encyclopædic in character, in which can be found the proceedings of distinguished societies of this country and of Europe, the work of the chief actors of medical progress in all parts of the world. Twelve thousand subscribers would give $60,000, this would insure $40,000 from advertisements, making an income of $100,000, which would sustain one of the grandest journals in the world.

"The *British Medical Journal* in fifteen years has fourteen thousand subscribers, and an income of $125,000. May we not hope to reach this? and when we do, who can compass the good which the American Medical Association will accomplish?"

THE MEDICAL AND SURGICAL LIBRARY AND MUSEUM AT WASHINGTON.

Another important factor in professional culture is the great Library and Museum, at Washington, evoked by the efforts of an American bred physician, John S. Billings. The Library of the Surgeon-General's office of the army now contains 92,000 volumes, and 137,000 pamphlets, being the largest collection of medical literature in the world, and it is not only the largest, but the most useful. This is because it has an "Index Catalogue," which not only shows what the library has of the works of any author, but, for any given subject, indicates all the original articles in journals and transactions, as well as the books and pamphlets which relate to it, and thus forms a medical bibliography which saves an enormous amount of time and labor to those engaged in medical literary research. This catalogue is being published at the rate of one volume a year, nine volumes have been issued, and six more will complete the work. The Army Medical Museum is a great pathological school, and now contains over fifteen thousand specimens, being one of the eight largest museums in the world, and richer than any other in illustrations of military medicine and surgery. This Library and Museum are national in scope and character. They have at last been securely placed in a fire-proof building, well adapted to their needs, thanks to the efforts of the medical profession, and we should see to it that they are maintained and increased to the highest degree of completeness and efficiency.

The medical profession asks very little of the general Government, but it does ask that these two institutions shall be made as useful as possible. The number of copies of the "Index Catalogue" which Congress authorizes to be published is hardly sufficient to meet the demand, and the repeated requests for authority to publish an illustrated catalogue of the Museum for distribution to the profession, have not yet received any attention from Congress, and it is time we took the matter in hand. When we, who are the family physicians of our senators and members, say to them that this is a thing that ought to be done and must be done, it is pretty certain that it will be done. There is nothing that will do more to promote higher medical education, to stimulate research, and to crown American medicine with honor than to give ample means to this great Library and Museum to obtain materials, and to publish widely the results.

"MEDICAL AND SURGICAL HISTORY OF THE WAR."

This matchless record of military medicine and surgery, is a marked testimony to the profession of our land. Let us for a moment compare it with similar work elsewhere. After the great Crimean war was over, its experiences

collected, weighed, and analyzed, how strange, in the light of present surgery, and in what contrast with the lessons taught in our great conflict, is the record of McLeod upon one vital operation—trephining for fractures of the skull. In his "Notes on the Surgery of the Crimean War," that distinguished gentleman says:

"If any patients were lost from not having been operated upon, I never saw any of them, but I do know of some patients who died because they were subjected to operation."

And what a fearful commentary upon the military surgery of that campaign McLeod makes when he writes:

"Thus it would seem as if severe fatigue, irregular, and it might be intemperate, diet, are less injurious to men with fracture of the skull than the probings, pickings, and trephinings which form the more orthodox and approved practice."

It may be truly said that the judicious use of the trephine during the conflict between the States, supplemented after the war by American surgeons, especially by one of our fellows, Professor W. T. Briggs, led up, led surely, safely, and steadily to the achievements of Victor Horsley, the master of us all in brain surgery.

MEDICAL SOCIETIES.

Our medical societies, local and national, are great factors in professional progress. Not alone are they valuable for their social opportunities, but in and through them a vast amount of valuable matter is presented.

MEDICAL LITERATURE.

Had Sidney Smith been a physician and given to reading, he would not, even in 1850, have asked the questions: "Who reads an American book?" "What does the world owe to American physicians or surgeons?"

This reverend gentleman, this famous critic, could not have heard of Ephraim McDowell, whose brief paper, detailing his first three cases of ovariotomy, published in *The Philadelphia Repertory*, in 1817, was of more value, did more for the conservation of human life, than a score of ordinary publications. Our first half century may be poor in books, but it abounded in strong, brave, conscientious, and devoted men, men who, with the most limited resources, accomplished the grandest results. They compelled success because they deserved it.

The ink was hardly dry upon that cynical pen when anæsthesia was presented by the profession, so poor, as he supposed, in valuable works.

But what country or age can match, in great contributions to the relief of the suffering, McDowell, Sims, Bigelow, Sayre, Batty, and Emmett, and that trinity of men—Wells, Morton, and Jackson—who gave anæsthesia to the world. Think of anæsthesia and of its influence upon the progress of medicine and surgery. But yesterday a writer in the London *Lancet* gave a graphic history of its reception in London; how the great Liston, having a patient who could not nerve himself up to the point of consenting to have a limb amputated for strumous disease of the knee-joint, decided that, "if the insensibility could be insured and maintained for one minute, he would amputate." Reflect for a moment on the hesitancy of the great surgeon of University College Hospital, as he stood by the side of that patient; he could hardly believe the novel report as it came from over the sea. Willing and anxious as he was to operate, he hesitated to urge the poor patient to make the experiment—experiment it then was. In a week, however, it was legitimate practice all over the world.

The heart of every American physician is filled with thankfulness when he remembers that, in the Providence of God, this great boon to humanity was vouchsafed to his country. The very ground upon which stands Massachusetts Hospital is sacred to us all. Associated with the discoverers must ever be the name of Dr. Hayward, who performed the first operation under the strange letheon. Previous to this, operative surgery was slow, tedious, and almost cruel. Contrast it to-day with what it was previous to 1847. What grand strides it has made under the direct support of anæsthesia and its almost equal co-laborer, antisepsis; the great cavities are invaded, and invaded safely; the abdomen has become a familiar field, and who can forecast the surgery of the brain?

Since Emmett's operation we hear no more, neither in this country nor abroad—neither in London nor Berlin, neither in Paris nor Vienna—of that culmination, that *ultima thule* of ignorance, "ulceration of the os." What a disgrace that term was to the surgery of the world!

The ignorance in diagnosis was only surpassed by the cruel treatment which it evoked, the application of caustics to the tender everted membrane of the cervical canal.

Has the operation, Bigelow's litholapaxy, the crushing and evacuation of a stone at one sitting, been truly estimated? Its adoption in one celebrated case might have changed the destinies of Europe. Previous to Bigelow, lithotrity was an uncertain, and, in most hands, a cruel operation: "Crush all possible at a short sitting, and allow the fragments to pass *via naturalis*." Bigelow realized that if anæsthesia is safe for two minutes, it is safe for two hours or more; hence, he said, "Crush it at once, and evacuate the bladder by an aspirator." The operation, in proper cases, is as practical as the description is brief and efficient.

The accomplished Edmund Owen, M.B., F.R.C.S., upon calculus, says: "With rare exceptions, only two operations are now practised—supra-pubic lithotomy and crushing, with evacuation at a single sitting." A high compliment from an eminent authority.

The story of Ephraim McDowell, though so often repeated, humanity never tires of hearing. To us he belongs, and to us only; we cannot share his fame with another; we would not if we could. Who can measure the relief which his operation has bestowed upon suffering woman?—not only woman, for his was the genius which opened the way for laparotomy in both sexes.

CLOUDS.

What has been accomplished by the profession in this country, self-reliant, and as we have heretofore said, without Governmental or social support, is certainly worthy of congratulation, and gives grounds for hopes of a rosy-hued future; but, alas! there are some dark clouds to be seen—some spots on our sun of promise! Have we inherent defects in our organic law—our *esprit de corps?*

Upon the face of our promising future some omens of evil appear, indications which look not up but down, not forward but backward, not to the elevation but rather toward the degradation of our profession. Heretofore we were an organization into which no species of fraud could enter—pretension, ignorant pretension, stopped at the door. No *ism* or *pathy* was admitted; something more than a diploma, "a legal diploma," was required—a clean bill of conduct, free from false assumption, assumption of universal knowledge, of specific remedies, of imaginary potencies; in fact of all shams and false claims, a guild in which there was the greatest freedom for the truth, the largest liberty for the right. No vender of secret remedies was admitted, because of the ignorant presumption in which they were conceived and propagated; but, alas, that we should have fallen upon the evil times when "patented processes" are attempted, when "processes" of valuable remedies are kept secret. These remedies with "patent processes" are in daily use. This is one of the dark spots in the picture. It came in with the "legally qualified practitioner." What is antipyrin, antifebrin, salol, sulfonal? The reliant patient may well propound such questions. Who can answer them? Are we relegated at one fell move back into outer darkness, the associates of venders of "secret remedies," of "patented processes?" What higher is a "patented process" than a "patented nostrum?" The profession was never so low as to countenance the latter; but have we not, in

these later days, become propagandists of patented, and therefore secret, processes?

LAWS FOR THE REGULATION OF THE PRACTICE OF MEDICINE.

It may be asked, has the standard of professional excellence been raised by laws enacted in many of the States for the regulation of the practice of medicine?

These laws banish the poor creatures without diplomas, but make respectable, *quasi*-respectable, all who have so-called diplomas from whatever source. Shams and pretenders are in this way made "legal," and claim whatever protection and recognition that term may give or imply. A chartered institution, in most of the States, represents a formal application for incorporation to a Secretary of State, the signature of that officer and nothing more. The process of graduating from such—the faculty often consisting of but a single person, or a man and his wife—would hardly be called a farce; the subject is too serious. "Legally qualified!" think of it; and yet this legally qualified creature will claim and expect to meet the highest and the purest. Is this an advance upon the requirements of the Code, the morals and *esprit de corps* of which have never been questioned?

What has been the effect of these diplomas? Let any candid man answer. Have they not tended to make vice and presumptuous ignorance respectable?

Let us be true to ourselves; pitch cannot be touched without defilement. Our profession must be kept pure, or else it will degenerate and sink to the level of a trade.

In State Boards of Health, by the side of physicians, we find these "legally qualified" practitioners. Where lies the responsibility? Is it with us? Our self-examination on this subject should be searching. If we have failed in our duties to humanity, let us be swift to acknowledge it, and be still more eager to correct our error.

The presence of this body of professional gentlemen, representing our entire country, furnishes sufficient argument for the existence of a National Organization; one embracing the virtue and strength of the profession, one to which all questions should be referred for just and final decision. Questions will arise, differences of opinion will occur between honest men. We must have some tribunal, some body, to which these questions, these differences of opinion, can be relegated for solution. The golden rule is a principle, not a law; it cannot interpret itself. Its application to life in detail must be defined. In this respect we are like other men and other organizations. Our morale, however, is higher; it has a zeal, a spirit, a hope and confidence peculiarly our own. If we would have our organization pure, we should make it strong—strong enough to eliminate all that is not true or truthful. We are mortals; not transcendentalists. We cannot live as the commune. We must have laws; remembering always that they are not made for the righteous, but for the sinner. "They that be whole need not a physician, but they that are sick." I will not attempt to defend the ethics of our profession. It would be a poor compliment to your intelligence, to your manhood; for there is not a clause in our Code which a gentleman could not cheerfully obey. Organize whatever we may please—associations of Specialists, of Physicians, of Surgeons, Academies of Physicians, Congresses of Physicians and Surgeons—but let us not lose our loyalty to this parent association. Projected almost half a century ago, when medical societies were few, it has annually convened—in the North, in the South, in the East, in the West, and in the far West, on the Pacific shore; if you will examine its yearly roster you will find that it embraced the best and the wisest. Almost all who were present at the beginning are at rest; their places have been filled by worthy men. Thus yearly new life, new men being added, this Association cannot grow old.

"When a people hold their lives and property as nothing, the enemy has already suffered defeat." So, too, when virtue will not compromise with vice, the victory, although it may be long delayed, will surely come.

Of the American Medical Association let us unite in saying, *Esto perpetua!*

SECOND DAY, WEDNESDAY, JUNE 26TH.

The meeting was called to order at 10 A.M. Prayer was offered by Right Rev. Thomas M. Clark (Episc.), Bishop of Rhode Island. The

ADDRESS ON GENERAL MEDICINE

was then delivered by WILLIAM PEPPER, M.D., of Philadelphia. This address consisted of thoughts suggested by the life of Benjamin Rush. Time has dealt tenderly with his memory, as he will always remain among the first of our great physicians. His political services, although great, were less important than those he rendered to science. The political appointments of Rush were laborious and unprofitable, as he refused pay for public services. In 1785 he started the Philadelphia Dispensary, and this example was followed by many others. He was profoundly interested in moral philosophy, and attracted general attention by his writings in this department. Among the first to indict capital punishment, he started a powerful plea for reforming the penal code. In range of subjects and grasp of them, it is hard to equal him.

A TRUE SOCIAL REFORMER.

In 1771 Rush denounced slavery, and he was likewise an opponent of ardent spirits, although not a prohibitionist. He also opposed the use of tobacco. Versatility and activity characterized his life.

A LEADER IN ALL SUBJECTS.

Rush attained the highest rank in letters. His medical lectures were eloquent and logical. He delivered some great orations; for example, that on Cullen.

FACTS ARE THE MORALITY OF MEDICINE.

His arguments were compact, with clearness, force, and flexibility of style. In the vital matter of education Rush was active and progressive, and much ahead of his time. He labored to establish our public school system, and defended the Bible as a school-book. Universal education is the only safety of the republic. The evidences of genuine and unaffected piety show in his writings and career. The subject of religion was constantly touched upon with sincerity and an absence of sectarianism. He was active in philanthropy, education, and religion to the end of his life, but Rush was before all else a physician. The study of medicine was followed with a passionate intensity. From 1789 to 1813 Rush's history is largely the history of American medicine. He was influenced by the genius of Sydenham in medicine, and of Franklin in philanthropy. Sydenham was a true Baconian in his close observation of facts. Posterity judges the pupil to be worthy of the master. The excellence of the teacher was shown by the testimony of his pupils. Students went to Philadelphia from all parts of the country to profit by his teachings. Rush was the earliest advocate of

ADVANCED MEDICAL EDUCATION.

With reference to his advocacy of bleeding, we must not judge him too hastily. He bled more systematically than Sydenham, but in later epidemics he somewhat restricted this practice. The external application of cold was employed as well. In the record of the fever epidemic of 1792, bleeding and purging were employed in the early period of attack. For this he was much vilified and slandered, but he had first begun his treatment with the use of stimulants, and had got poor results. He considered his results were much better after using evacuants. Rush fought for what he considered an important principle. It is difficult to believe that in certain epidemics, and in cer-

tain stages of disease, the bleeding practice of Sydenham and Rush did not do good. They did not bleed for the name of disease, as some of their followers did, but carefully considered the condition of each case. In all specific diseases, it is a question of

SOIL AS WELL AS OF MICROBES.

While Rush's work was pre-eminent in fevers, he was likewise eminent in alienism, and likewise in the treatment of chronic diseases.

Dr. Pepper concluded his address by making an appeal for the Rush monument.

Dr. A. L. Gihon, Chairman of the Rush Monument Committee, next gave his report. He was not able to report progress. At the present rate, the members of the committee will not live to see the consummation of this work. Other professions and callings are abundantly represented by monuments.

THE MEDICAL PROFESSION DOES NOT RECEIVE SUFFICIENT SOCIAL AND PUBLIC RECOGNITION.

The medical profession in the United States numbers one hundred thousand, and it was thought that if forty thousand would each contribute $1 a noble monument of art could be built. This hope has not been realized. At the end of five years only $1,000 has been received. This, to a certain extent, is the history of all monuments.

At the end of this report $264.50 was collected from the members present.

The following

AMENDMENT TO THE CONSTITUTION

was carried: "Strike out the last clause or paragraph of Section VII., relating to individually affixing names to the constitution and regulations of this Association."

Third Day—Thursday, June 27th.

Prayer was offered by Rev. James Cogle.

A memorial from the American Social Science Association was read, in which the American Medical Association was requested to take steps to elevate the standard of medical education. It was suggested particularly that a more advanced preliminary education be insisted upon before students are allowed to begin the study of medicine. The memorial was accepted by the Association.

THE ADDRESS ON GENERAL SURGERY

was then given by Dr. Phineas S. Conner, of Cincinnati.

The surgery of the century has been of three periods, the pre-anæsthetic, the anæsthetic, and the modern one. Operative brilliancy characterized the first. The suffering inseparably connected with the use of the knife and the nervous depression resulting therefrom was to be limited chiefly by celerity of execution; hence, the swift-moving hand was an essential part of the equipment of the fittest surgeon.

When, in the amphitheatre of the Massachusetts General Hospital, "the problem of surgical anæsthesia was definitively solved," a new period began. Pain was no more and it was permitted to examine earlier and more thoroughly, to remove more extensively, and to operate successfully in regions previously altogether, or in great measure, beyond the reach of art. For twenty years or more, progress was in the line of diagnosis, of development of new and better methods of operating, of extension of the range of surgical interference. Time was no longer an element of prime importance, and the work was regarded as quickly enough done when well and thoroughly done—too much so, in fact, for not seldom the best interests of the patient have been jeopardized by unnecessary delay in execution, that would not have occurred but for the existing profound insensibility. But though operations in this anæsthetic period were without much of the terrors of the olden time, yet they fell far short of producing the wished-for result in preservation of life and early restoration to health. Wound complications were still as ever the bane of surgery, and too often the wisest planned and best executed operation resulted in failure because of the supervention of one form or other of septic infection.

It is scarcely twenty years since patient investigation, careful experimentation and practical testing began to throw strong, clear light upon that most obscure of the subjects of medical study, the causes of disease. As never before in the history of medicine truly scientific methods of research have been adopted and pursued by a multitude of trained observers in all civilized countries, and surgery has entered upon its scientific period, in which operator and patient are profiting by the labors of the chemist, the botanist, the physiologist, the physician, equally with those of the practical and experimental surgeon. It seems but yesterday when Lister's early papers startled the world. It is but twenty-two years since the first one was published, yet what enormous advances since then in knowledge, in treatment, and in the field of operative interference! A new department of science, surgical bacteriology, has been created (for what was done prior to 1867 may, for practical purposes, be left out of consideration), and in its development has been worked out the mycotic origin of all those pathological processes looked upon as inseparable from traumatisms, or almost necessarily associated with them if severe. Suppurations, gangrene, septic infection, erysipelas, tetanus, we know to depend upon the presence or the action of one or other of definite organisms that may be isolated, cultivated, and inoculated. Recognizing the cause, it has been comparatively easy to devise methods, more or less perfect in action, to prevent the development or neutralize the influence of it, and there has been worked out an antiseptic and aseptic wound treatment, the results of which are simply marvellous. But just here I must protest against the wisdom or the justice of the sweeping declaration of a few enthusiasts, who see in other than speedy recovery after injury or operation, evidences of what they are pleased to consider criminal ignorance or neglect.

The existing strong probability that in any given case septic infection might be prevented has given warrant for the performance of operations that in pre-aseptic days were not to be thought of.

Intestinal surgery, that so short a time ago meant scarcely more than the removal of an ovarian tumor, too often carried until death was evidently fast approaching, now includes operations upon almost every part of each hollow and solid viscus, and laparotomy has taken its place, as a safe, proper, and often indispensable prerequisite to the determination of obscure disease. Penetrating and perforating gunshot wounds, so generally fatal when treated by rest and opium, have in at least forty cases been recovered from after section and suture, and there are now but few surgeons still unconvinced of the wisdom of early active interference. At our last meeting Senn's carefully elaborated and beautiful demonstrations set forth a means of determining the existence and location of intestinal wounds, that if safe, as it has thus far seemed to be, will remove the greatest objection to laparotomy in these cases—the uncertainty in the earlier hours of bowel perforation—and prevent what otherwise will occur, the overlooking of one or more lesions. It is not to be expected that all, or any close approximation to all, of these very dangerous wounds will be saved by early operation, for great injury will ordinarily be produced by the bullet, be it large or small; but every case that recovers after section and suture may fairly be considered as rescued from an otherwise almost inevitable death. Unquestionably the laying open of the peritoneum and operating upon an abdominal organ has at times been carried too far. Useless work has been performed, and life has been sacrificed, for it is not true (so far, certainly, as operators in general are concerned) that abdominal section is in itself without danger, doing no harm if it accomplishes no good. But not a day goes by that, somewhere or other,

life is not prolonged, and comfort secured by an intraperitoneal ligation, suture, anastomosis, or excision, rendered proper, may we not say possible, only by the aseptic results of scientific discovery and experimentation.

So, too, the diseases and injuries of the other great cavities are being attacked by the surgeon's knife, guided by the diagnostic knowledge, the localizing exactness, and the technical skill of the physician, the physiologist, and the vivisector.

There has been but a beginning of intrathoracic surgery, though for years empyemas have been treated by free incisions, supplemented not seldom by extensive excisions of portions of the chest-wall, and even in preaseptic days deeply lodged foreign bodies were removed. Only very recently has the lung been cut into for the evacuation of abscesses and the treatment of gangrenous areas, such pneumototomies, resulting favorably in one-half of the reported cases; and as yet, but few subpleural tumors have been attacked. There is every reason for believing that in the near future surgery will be able to render great service to the subjects of not a few forms of thoracic disease now regarded as beyond the reach of art.

The most recent and the most brilliant triumphs have been in the treatment of diseases and injuries of the brain and cord. Nowhere else have our art and science so joined hands in affording relief as here. Tumors removed, foreign bodies taken away and their tracks drained, convulsion-centres excised, serous effusions tapped, life preserved, and comfort secured; so reads the record. Much remains to be done in the determination of the trouble, the exact localization of the mischief, the perfection of technique. Not seldom mistakes will be made, errors committed, but it will be more and more demonstrated that the trained mind and the skilful hand working together can recognize and successfully treat otherwise irremediable affections within the skull and the spinal column.

As the operative procedures necessary for the exposure and removal of the spinous processes and laminæ of the vertebræ are but little dangerous, and as septic meningitis can almost certainly be prevented, a change may reasonably be looked for in the treatment of vertebral fractures, especially those in the lower half of the column. Up to this time the cases in which active interference has been made have almost always been those of long duration, in which existing inflammatory changes in the cord, if nothing worse, could not but prevent any favorable result; but even in these, of late, the patient has been none the worse for the operation. Without doubt, early removal of pressure, whether made by bone or blood it matters not, would save many an one from all those deplorable conditions consequent upon myelitis with which we are unfortunately too familiar.

Is there any good reason why spine fractures should not be treated as skull fractures? and who would now for a moment think of rest and position as the routine treatment of the latter injuries?

But in this scientific period there has been much more accomplished than extension of the range of operative interference, great and important as this has been. As never before it has been possible to preserve damaged parts and to retain important functions, to replace completely detached pieces of bone, and secure adhesion as perfect as of the fragments in a simple fracture, to transfer large areas of integument and ingraft pieces of bone, to supply deficiencies in soft or hard parts by skin or bone from dog, rabbit, chicken, or frog. Every department of conservative surgery has been and will yet more be benefited by the preventing of the evils consequent upon the action of minute organisms.

The two diseases that produce the widest destruction to part and to life are tuberculosis and cancer. The former, that until the discovery of its causative bacillus was regarded as of rare occurrence in parts belonging to the domain of surgery, is now known to be the producer of the vast proportion of the diseases of bones and joints, and of many of those attacking the skin and more external organs.

Primarily and often for a long time local, if allowed to go on unchecked it affects other and remote regions, perhaps rapidly becoming generalized. But what has been learned respecting it? That it may attack any part of the blood circulation which is disturbed by general enfeeblement or local injury of ordinarily not severe character; that the bacilli may be destroyed or become encapsulated; that the softened tissues may, in like manner, be taken up and carried off, or shut in temporarily or permanently; that if the diseased focus be completely removed, as it often may, the part and the whole are as if it had never existed, except so far as function is disturbed by the loss of what has been taken away and by the scar tissue resulting. How has treatment been affected by this knowledge? It is of prime importance that early diagnosis be made. Located in bone or joint and detected while yet limited, prolonged rest, as absolute as possible, will, in the majority of cases, certainly in young subjects, secure destruction, absorption, or encapsulation of organisms or affected cells with resulting restoration to health. Advanced to the stage of caseation and liquefaction, rest may yet be followed by recovery, though ordinarily free drainage, with or without associated removal of the infected tissue, will be of great advantage. Injection of agents, such as iodoform or the acid phosphate of lime, that will destroy the bacilli and the tuberculous masses, may produce the wished-for cure. But ordinarily it will be better, indeed generally necessary, to remove the affected area either by formal or informal excision or by amputation. Whether diseased joints are best treated by arthrectomies or by typical excisions is one of the questions still *sub judice*, though in the last three years, as never before, it has been shown that former removals of the larger articulations can, in a large proportion of cases, be followed by early repair and solidification without suppuration or constitutional disturbance—even at times with recovery of original function. Though it is not likely that it can ever be said with truth that the days of the lame and the hump-backed have gone by, because of neglect, delay, or generalization of the pathological process, yet we have good reason to believe that further advances in knowledge of the development and extension of the tuberculous disease will enable the surgeons of the future to so limit, ameliorate, and cure the surgical tuberculous affections as that they will no longer constitute one of the most important and destructive of the external diseases.

Of cancer it may with truth be said we know very little; yet of nothing do we more need knowledge. Much less often met with than tuberculous disease, it is yet of not infrequent occurrence. In our eight largest cities (Boston, New York, Brooklyn, Philadelphia, Baltimore, Chicago, St. Louis, and Cincinnati) during the five years ending Dec. 31, 1888, of 579,684 deaths from all causes 13,094 were from cancer, 2.18 per cent., and as we all know the disease is not peculiarly an urban one. In five of the eight cities (New York, Chicago, Cincinnati, Brooklyn, and St. Louis) the death-rate was much the same, being in the order given 2.1, 2, 2, 1.94, 1.93 per cent. In Boston it was highest, being 2.98 per cent. In Baltimore it was 2.4 per cent., and in Philadelphia 2.28 per cent. In Cincinnati in the last year the percentage reached 2.6 per cent., while in 1868 it was but 0.55; an altogether exceptional rate, however, as only once since has it fallen below 1 per cent., in 1870, when it was 0.8. For these figures I am indebted to the Health Officer, Dr. Stanton. One in fifty, then, of the deaths, in an aggregate city population of over five millions, is due to this disease, and if we have regard only to the mortality of those within the cancer age, *i.e.*, more than thirty-five years old, about one in twenty of the deaths is thus produced. Even among the carefully selected adult individuals carrying life insurance, who are free, or are supposed to be, from family predisposition to cancer, from 2.5 to 3.5 per cent. of the mortality is from this disease. The statistics just mentioned, and particularly the marked

contrast between the high death-rate in Boston and the low one in St. Louis, give but little support to the theory of Haviland, that low lying lands subject to frequent overflows are those in which the disease is most prevalent.

In preparing the mortality statistics of the census of 1880 Dr. Billings found that the disease was most prevalent in New England and Southern California, and least so in the South and upon the Mississippi, It is to be hoped that in the preparation of the vital statistics of the next census such attention may be given to this subject of occurrence and distribution and such full and complete reports secured as will add materially to our knowledge, and go far toward determining the correctness or incorrectness of the views of the English writer named. Care should be taken to separate if possible cases of sarcoma from those of cancer.

Hirsch to the contrary notwithstanding, this affection is becoming more common throughout the civilized world, certainly is so in our own country and in Great Britain. Increased accuracy of diagnosis will not account for a doubling in twenty years of its mortality rate in Massachusetts or in Cincinnati, or in less than twice twenty years in England. Frequently, if not usually, attacking individuals in good general health (though oftentimes appearing soon after a period of marked mental anxiety and depression), it has regard neither to social conditions nor hygienic surroundings. Unlike consumption, which is often of limited duration, ending in recovery, and at the worst, ordinarily bringing death gently, cancer left to itself very rarely is spontaneously eliminated, is almost inevitably destructive to part and to life, and is often attended with severe physical and mental suffering.

What is its starting-point? an unused, long-dormant embryonic cell, at length aroused to activity by local irritation, general enfeeblement, or nervous exhaustion? In all probability, no. An abnormal epithelial development, abnormal because unconfined within its normal limits. But why unconfined? An epithelial cell undergoing proper degenerative changes, but arrested at some point short of its complete alteration. What stops its retrograde movement? is it of mycotic origin? That it should be so would hardly be more strange than that lupus or lepra should be. That it is so has not yet been proved. The many investigations that have been made, some of them for a time apparently fruitful, have thus far failed to discover a causative bacillus, unless further and extended cultivations and inoculations shall prove that Kübasoff has actually found it. Experimental inoculations have again and again produced no specific result, but Lampiasi has claimed that by using a bacillus culture from the blood he succeeded in causing in a healthy part of the patient's skin the growth of a nodule having "an alveolar stroma with wide meshes, which contained many epithelial cells of different forms and sizes;" and Hanan has twice successfully transplanted from rat to rat.

No more inviting field is open to the bacteriologists and experimenters of our country (and we have a number of them, as also well-equipped laboratories) than this very one of cancer. Cases are numerous, specimens are being daily secured, and there is no reason why America should not now do full part in settling the vexed questions of nature and origin. The imperative necessities of a struggle for existence, and the intense practicality of a new and developing country, have heretofore prevented any but the very few filled with enthusiasm or independent of fortune from engaging in purely scientific studies involving minute investigation and patient labor, with often no apparent practical outcome. But the times are changing, and the profession of our country may, and doubtless will ere long, be as well and favorably known in biological research as it has been and is in relation to ovariotomy, to ether, to the hip, to the treatment of stone, to the surgical diseases of women, to abdominal section, to a multitude of affections and the means of treating them.

As we see it in lip, or breast, or uterus, or stomach, or it matters not what part or organ, is cancer a local disease, or but a local manifestation of a constitutional state? The question is still an open one, though the great majority of pathologists and clinicians are now agreed that wherever seated it is primarily and for a time purely local, whatever may be the general conditions, inherited or acquired, that permit or favor its development. If not of limited area and capable of complete removal, operative interference can be justified only on the ground of affording temporary relief—unfortunately all that is accomplished in the majority of cases submitted to the knife. But there is great encouragement in the knowledge that a certain percentage of patients operated upon do recover; that is, remain free from recurrence for three or more years; and that this percentage is larger or smaller according as the disease is so situated as to be early detected and thoroughly removed, or the contrary. Located in the lower lip or the cervix uteri, for example, two out of five patients operated upon get well, in the breast one in eight. Why this great difference? Because, we may believe, of the site itself and of the degree and rapidity of extension in parts immediately adjacent, and of glandular involvement; in other words, of the likelihood of early and the possibility of complete extirpation, or the opposite. How are to be regarded those cases in which, after five, ten, or twenty years of apparently perfect health, the disease again shows itself and destroys life? As of long quiescence of infected and infecting cells, or of a new and independent affection? The latter explanation certainly makes a far less demand upon our credulity, and it is no more strange that there should be a second than a first attack in a person and tissues possessing an undetermined and unknown receptivity, and such there certainly must be that cancer may be developed at all.

Of nothing are we more certain than of the immense advantage there is in early recognition and speedy removal; and, on the other hand, of the utter uselessness, so far at least as the ultimate result is concerned, of any surgical interference after a wide extension has taken place.

In perfecting, therefore, the means of establishing diagnosis at an early day lies an important work in the future. Though consideration of age, of location, of pre-existing long-continued irritation, go far toward settling the nature of a given tumor, and upon such estimation of probabilities action may generally be safely taken, yet, as a rule, certainty of the character of the growth can only be had after scientific determination of its anatomical constitution. Whatever, then, makes it possible to safely, easily, and without pain remove for microscopic examination a sufficiently extensive piece of the mass to show its deep as well as superficial structure, is of much practical value. A convenient and promising little instrument has lately been given to the profession by Dr. Collins Warren, of Boston.

Physiological and chemical investigations have furnished us with early and reliable evidence of the existence of cancer of the stomach in absence of the hydrochloric acid from the secretions of that viscus; may not kindred investigations give us like aid when other organs are affected?

The modern and scientific wound treatment now enables the surgeon to remove more extensively and at the same time safely, so that active interference may reasonably be expected to be, and is, attended with much better results than could be looked for a few years ago. Much of the work, though, that in the last decade has been done upon internal cancers has been of questionable utility, chiefly because of its late performance.

What will the future reveal respecting the non-operative treatment? Will a drug or drugs be found to secure destruction and removal of the morbid mass? May the moderate continued electric current, or powerful interrupted currents, "flashed through," prove to produce, as has been claimed for them, entire disappearance of the diseased cells? Can some pathogenic organism be inoculated that, without killing the patient, will break down

the malignant growth? We all know what has been done with the micrococcus of erysipelas.

In nothing could this Association do more than in determining by collective investigation and thorough committee work the frequency of occurrence of carcinoma in the country, as a whole, and in its several States the relation borne (if any) to geological formation, the age of appearance, the relative affection of parts and organs, the influence of therapeutic treatment, and the duration of life with and without operation. Five years of such work would suffice to accumulate a mass of statistics of very great value, the study of which could not but advance the best interests of patients and practitioners; and in this as in everything else, "many hands make light work." To physicians, surgeons, and therapeutists the subject is one of prime importance; and only by combined scientific and practical work can it be determined what excites and produces the disease and what can secure its relief.

As we survey the advances, etiological, diagnostic, and therapeutic, made in the few years just past that are of the scientific period, and consider, even in the most hurried way, the problems that are yet awaiting solution, problems relating to the nature, origin, and treatment of the diseases and injuries of parts within the domain of surgery, what may we not reasonably anticipate as the future of our science and art. Accidents must occur, diseases will prevail, no matter how great the triumphs of preventive medicine. Surgical pathology is but in its infancy. Years ago it was declared that operative surgery had reached its climax. Yet since then operations have over and again been done within abdomen, chest, and skull, upon the larynx, throat, and spinal cord, that in boldness of conception and brilliancy of execution have no parallel in the history of medicine. The end is not yet; nor will it be while, the world over, there are active minds and cunning hands busied with the determination of the existence and extent of surgical affections, and ready and able to remove them, aided more and more by the labors of investigators in many departments of science, general as well as medical. Year by year he who may deliver the address on surgery will be able to report doubts removed, discoveries made, remedies employed, and operations done.

The report of the Treasurer, DR. R. J. DUNGLISON, of Philadelphia, showed the finances of the Association to be in a satisfactory condition.

The Nominating Committee then made their report.

The next meeting is to be held at Nashville, Tenn., on the third Tuesday in May, 1890.

The following officers were announced: *President*—E. M. Moore, of New York; *First Vice-President*—J. W. Jackson, of Missouri; *Second Vice-President*—W. W. Kimball, of Minnesota; *Third Vice-President*—J. H. Warren, of Massachusetts; *Fourth Vice President*—T. B. Evans, of Maryland; *Treasurer*—R. J. Dunglison, of Pennsylvania; *Permanent Secretary*—W. B. Atkinson, of Pennsylvania; *Librarian*—C. H. A. Kleinschmidt, D. C. To deliver Address on General Medicine—Dr. N. S. Davis, of Illinois; General Surgery—Hunter McGuire, of Virginia; State Medicine—Alfred L. Carroll, of New York.

HON. GEORGE BANCROFT was presented to the Association amid great applause.

SIR JAMES GRANT, of Ottawa, was next presented and made a few remarks. The speaker first dwelt upon advances made during the past fifty years in the treatment of insanity. The line of this improvement was all in the direction of more humane methods; formerly "the insane were treated as criminals," but now they are treated and studied as other sick people.

A graceful tribute to the life and services of the late Dr. John Gray, of Utica, was next given. The speaker referred to the advances made in the surgery of the thorax, toward which American physicians had contributed so much. Preventive medicine and hygiene were dwelt upon, and the speaker thought that improved drainage and ventilation had contributed much toward the increase of health and life.

Medical education and examination were treated at some length. The crowding of the medical profession by poorly educated men was deplored. The best way to weed out irregular practitioners is to require "a rigid preliminary training." By this method the Medical Council of Ontario has succeeded in accomplishing very good results. Finally, Canadians are always glad to come to the United States because both are one people with common customs and literature, and with the same spirit of independence. The younger members of the Association were advised to record cases and write, not only for their own good, but for that of the general profession.

SECTION OF THE PRACTICE OF MEDICINE, MATERIA MEDICA, AND PHYSIOLOGY.

F. C. SHATTUCK, M.D., CHAIRMAN.

FIRST DAY, TUESDAY, JUNE 25TH.

THE Section opened with the address by THE CHAIRMAN, who read a paper entitled

A REVIEW OF PROGRESS.

In the treatment of pulmonary phthisis the inhalation of hot air has been tested and its intrapulmonary germicidal action is still unsolved. In the pathology of pancreatic disease Senn and Fitz rendered important service, and the latter has shown in his recent work that acute pancreatitis seems to be due to the extension of acute inflammation from neighboring organs. The diagnosis of pancreatic affections is thus shown to be not so difficult as was once supposed. Frerichs long ago, and Lancereaux more recently, have both called attention to the relation between atrophy of the pancreas and diabetes mellitus. In certain cases of diabetes the organism has lost its power of bringing the fatty acids to their normal end products, and in these cases diabetic coma is liable to occur. Graeber distinguishes the anæmia by a count of the red corpuscles and a hæmoglobin estimation. Hunter thinks that anæmia is an entity and probably depends on increased blood destruction in the liver. The chemical study of stomach disease has not given all that was hoped for it. The use of cold baths in typhoid fever still seems to be justified by favorable results. Sulphonal and amylene hydrate have proven themselves to be valuable additions to our list of remedies of this class. In the use of suspension in the treatment of locomotor ataxia, deductions cannot yet be drawn with certainty. On the whole the progress of medicine for the past year has been gradual but noticeable.

DR. CHARLES G. STOCKTON, of Buffalo, N. Y., read a paper

ON THE PASSAGE OF PORTAL BLOOD INTO THE GENERAL CIRCULATION, AND ITS PROBABLE RELATIONS TO TOXÆMIA.

After speaking of the difficulty of explaining the coma accompanying some diseases and their relation to the hepatic circulation and the inosculations and anastomoses in certain regions, he said that the portal blood underwent changes more or less before passing through the liver, and the blood of the portal vein was toxic These two facts have been proven by numerous studies in anatomy and physiology. Nature probably tries to prevent the toxæmia which is inevitable in so many cases by returning the blood through other anastomoses than through the liver.

DISCUSSION.

DR. WM. OSLER, of Baltimore, said he thought the facts stated were partly true, but the anatomical facts could not always explain those conditions. It depended much upon how the collateral compensatory circulation was established. Post-mortem examination often showed cirrhosis with no previous symptoms. The portal vein may be obliterated by fibroid condition, and yet no toxæmic effects may be shown.

Dr. W. S. Tremaine, U. S. A., said the portal circulation is a part of the venous circulation. We too often speak of them as different. The action of the liver is similar to that of a filter. We do not understand altogether the action of the liver. These toxic symptoms are due to defective action on the part of the liver, whatever this action may be. The blood is an organ, not a fluid. The action of digestion is carried on in the blood. Physiologists and pathologists know very little about clinical facts, and we should not draw wrong deductions. Some of these so-called facts are only theories. We should combine the two, and not take the theorist's opinion when he was not versed in clinical facts.

Dr. John H. Musser, of Philadelphia, thought the physiological facts were very ingeniously brought out, but he could not agree with the speaker altogether.

Dr. H. A. Hare, of Philadelphia, thought we had perhaps overlooked the fact that any capillary net-work is just as destructive to any poison in the blood as the capillaries in the liver. These discoveries were made by Schiff and Lautenbach. The liver is simply a large capillary net-work. Not all peptones are poisonous. A pure peptone will fail to cause fever, while a partial peptone will cause a rise of temperature. We inject peptone into the rectum and get no fever.

Dr. Cronyn said cirrhosis reduced the size of all the vessels in the liver which made the change of blood easily understood, Cholesterin was produced because the function of the liver was altered.

Dr. Lister spoke of his experience in two cases of hypertrophic cirrhosis of the liver and the effects of mercurials on this condition, such as the bichloride in small and repeated doses.

Dr. Stockton agreed with Dr. Osler, but held that it was not common for portal blood to flow in the general circulation.

Dr. G. R. Martine, of Glen's Falls, N. Y., read a paper with the subject

A NEW PLAN FOR THE TREATMENT OF PNEUMONIA,

the object of which was to regulate the heart's action by such a drug as veratrum viride, and not stimulating the heart at a time when the lungs were already too much engorged with blood. He thought stimulation of the heart did much harm when there was red hepatization.

Dr. I. E. Atkinson, of Baltimore, thought the veratrum viride treatment had been used long ago without much success. It produced alarming symptoms in small doses. Patients thus ill die more from heart failure than from being drowned in their own blood.

Dr. H. A. Hare said in the first stage we should give veratrum viride to abort the disease, and in the second stage he gave digitalis. Few cases of death occur from veratrum viride, as emesis prevents poison.

Dr. Cronyn thought no two cases should be treated alike.

Dr. Martine claimed that his plan was new in that no writer had told us when to give the drug (sedative), and hold the pulse below 80° F.

Dr. John H. Musser, of Philadelphia, read a paper on

SOME CLINICAL ASPECTS OF VOMITING.

After reviewing the act of vomiting, he divided the acts into direct and reflex. Changes in the organs of sense, etc., will also cause vomiting. The duration, time of day, character of vomitus should all be considered in looking for the cause. In naso-pharyngeal catarrh morning vomiting is not infrequent; in chronic uterine disease also. Sudden and painless vomiting in the aged is often one of the first symptoms of cerebral hemorrhage. There is no exhaustion in this kind. If collapse occur it may be uræmic vomiting. Prognosis is always grave in these conditions. In all conditions of vomiting the causes should be looked for in every one.

DISCUSSION.

Dr. Stockton thought it was difficult to go over all the causes which might cause vomiting. Chronic gastritis often occurs with naso-pharyngeal catarrh, which would explain the statement just made.

Dr. W. J. Scott, of Cleveland, said in naso-pharyngeal catarrh there was also chronic dilatation of the stomach with catarrhal conditions which would explain the facts stated by the reader.

Dr. I. E. Atkinson, of Baltimore, read a paper on

SOME OF THE RARER AND GRAVER FORMS OF CINCHONISM.

Cinchona and its allies are generally given without regard to idiosyncrasies. Intoxication, etc., which may occur as the result of cinchonism, may be very grave. The absolute frequency of cinchonism is not great, but worthy of notice. He had collected over fifty cases of quinine amaurosis, in which the blindness was present in nearly all. The vision is often affected without suspicion of the drug. In most cases the blindness occurs suddenly, but in many cases it may be gradual. It may occur within twenty-four hours. In all, or nearly all cases, the sight returns, but the eyes are often affected for a longer time, even after two years, and color-blindness often permanently results. The blindness is almost complete, the color-blindness is marked for a long time; the pupils are much dilated, the disks are white and pallid; there is contraction of the visual field; impairment of hearing is often noticed; some patients have anæsthesia of the cornea, strabismus, etc. Knapp showed that relapses may occur with very small doses. The pathogenesis of quinine amaurosis is not at all understood, although many explanations have been offered. The dose of quinine sufficient to produce blindness is very variable. H. C. Wood had seen it after doses of twelve grains. Blindness always results when the causes are lethal. Immense doses are taken without causing blindness, so that it undoubtedly occurs as an idiosyncrasy. Tinnitus aurium is common, but permanent deafness has never been recorded, even complete temporary deafness has probably never been observed. In those already deaf this deafness may be increased. In the ear there is much anæmia. Enormous doses of quinine are necessary to produce death, and fatal cases of cinchonism have rarely been recorded. The cardiac conditions described in the autopsies of the various fatal cases are very dissimilar. Sufficient attention has not been given to the dangerous and toxic effects of quinine in large doses.

Dr. H. A. Hare said as soon as quinine reaches the pyloric orifice it is precipitated and passes out unchanged, and this would explain the harmless effect.

Dr. Cronyn fully endorsed the opinion of Dr. Hare from a large experience.

Dr. W. J. Scott did not agree with the previous speakers at all. His experience had shown the good effects of large doses, and he thought the theory here did not bear out the facts, which no one with a large experience could deny. The unfavorable conditions were present before the patients took the dose.

Dr. Musser said most cases for which quinine was given were cases of malaria. In these cases small doses would control the paroxysms. Osler noticed the flagellate bodies in the blood would disappear after the use of very small doses of quinine.

Dr. Tremaine gave his experience, in which he said that in malarious districts large doses were necessary, and in non-malarious districts large doses did harm.

Dr. Cronyn spoke of Bence Jones' theory in regard to the effect of large doses of quinine on the appearance of the blood. He thought if too much of a drug were given the excess was passed off by the bowels.

Dr. H. A. Hare said that other substances showed this condition of the blood besides quinine, and this theory of Bence Jones did not hold good to-day.

Dr. Lister agreed with Dr. Cronyn, but thought that the combination of several drugs might be more effective.

Dr. Shattuck reminded the gentlemen that they were wandering from the subject, and called on Dr. Atkinson.

Dr. I. E. Atkinson, in conclusion said he only wished

to bring forward the one fact that excessive doses of quinine had been fatal. In reply to Dr. Hare he would refer to the habit of giving calomel before quinine, which increased the acidity of the gastric secretions. Hypodermic injections would obviate this. One case in a lifetime should prevent us from giving it too lavishly, and compel us to give it under the skin. He had collected fifty known cases, and probably there were many unrecorded cases.

Dr. Robert T. Edes, of Washington, D. C., then read a paper entitled

HYDRONEPHROSIS AND RENAL ATROPHY, ESPECIALLY AS CAUSED BY FUNCTIONAL DISORDERS OF MICTURITION,

in which he argued that serious renal troubles in children were not necessarily caused by constitutional disease but might find their etiology in the kidney itself.

Second Day, Wednesday, June 26th.

Dr. Francis Delafield read a paper entitled

CHRONIC ENDOCARDITIS

Few cases are more common than this disease, and it may be present within great variations, from a mere inconvenience to great distress on the part of the patient. Nearly all the most important symptoms of chronic endocarditis are due to the disturbances produced in the distribution of the blood throughout the body. It is not easy to say why, in some cases of chronic endocarditis, there are disturbances of the circulation, and why in other cases there are not. The disturbances of the circulation are due to the endocarditis, dilatation, and hypertrophy of the ventricles, inflammation or degeneration of the wall of the heart, inflammation of the coronary arteries, abnormal heart-action, and the associated pulmonary emphysema, chronic endarteritis, and chronic Bright's disease. These conditions, all of them, must be considered in connection with chronic endocarditis. In regard to the last condition mentioned, namely, chronic endarteritis and chronic Bright's disease, he found that albumen was present, casts less constant. Anæmia and dropsy are present, and the patient gets worse. Changes in structure much the same, however the symptoms may be. Arterial walls thickened. There are three forms of chronic nephritis: 1. Chronic nephritis with much exudation; serum exudes from blood-vessels to the urine; amount of urine varies; specific gravity is lower; albumen and casts are constant; patients do badly. 2. Nephritis with moderate exudation; urine diminished; specific gravity lower; no albumen or casts present unless patient does badly; liable to dypsnœa, headache. 3. Chronic nephritis with little or no disturbances; urine shows no change; they gradually grow worse and die.

DISCUSSION.

Dr. William Pepper, of Philadelphia, said he was glad to hear the author of the paper dwell on the changes in the arteries. Our knowledge of the nerve-ganglia about the heart is very defective. Rest in bed is important in the prevention of extension of the disease. In the cases where there is no sign of progressive lesions we should still be on our guard. In some cases bleeding does a great deal of good, even when the cases seem to be anæmic.

Dr. William Osler, of Baltimore, thought chronic endocarditis produced in itself no symptoms. So long as compensation is perfect the patient needs no help.

Dr. Osler then read a paper entitled

SENSORY ASPHASIA; WORD-BLINDNESS WITH HEMIANOPSIA.

About one dozen cases of word-blindness were now on record. The case reported was very typical. Patient could not pronounce words he saw, but could repeat them. He constantly misplaced words. He finally became paralyzed and died. There was softening on the surface of the brain, and deeper, as at the angular gyrus, and this softening was seen on the white matter, from the posterior horn of the gray matter, directly through to the surface. The word-blindness was undoubtedly due to the softening in the angular gyrus. The hemianopsia was due to a cutting off of the optic branches. The speaker also exhibited some

SPECIMENS OF BRAINS

prepared according to the Italian method, with zinc, zinc chloride, glycerine, etc.

Dr. James Tyson, of Philadelphia, read a paper entitled

THE INDUCTION OF PREMATURE LABOR IN BRIGHT'S DISEASE.

We should bring on premature labor: 1, In cases of Bright's disease where in previous pregnancies the symptoms had been extremely severe and dangerous; 2, in all primiparæ in whom there is Bright's disease previous to pregnancy; 3, those in which we have not the knowledge acquired in the previous cases. A large number of such cases terminate by miscarriage, and terminate well for the mother. It might not be a bad idea to examine the urine of every woman before marriage. A few cases may progress to full term without fatal issue, but these are exceptional cases. Each case must be decided on its own merits.

Dr. V. C. Vaughan, of Ann Arbor, Mich., thought the points raised by the speaker were very important, and his experience taught him to do the same, except in the case of primiparæ, where diet can do much by limiting the amount of proteid food.

Dr. I. E. Atkinson thought it was a bad precedent. In the primiparæ we get the most terrible results, and in his experience it was the contracted kidney which was the most to be dreaded. He waited in some cases until mild symptoms showed themselves, and then he brought about premature labor.

Dr. W. J. Scott, of Cleveland, O., did not think it was well to formulate such a rule, in every case, as Dr. Tyson suggested.

Dr. Carpenter, of Pottsville, also recorded his experience as against producing premature labor in primiparæ. He found bleeding and purging an efficient remedy.

Dr. J. G. Truax, of New York, said that his experience was that the patient would not submit to induction of premature labor if she did not feel badly, and this is especially true in the case of a mother desirous of offspring.

Dr. J. C. Wilson, of Philadelphia, thought the early recognition of the renal trouble was important, and that therefore the earliest possible examination of the urine should be made.

Dr. Tyson did not mean to say that premature labor should be induced in every primipara, but that in primiparæ it was very dangerous.

Dr. D. W. Prentiss, of Washington, D. C., read a paper on

THE PHARMACOPŒIA OF 1890,

in which he laid stress on the fact that in 1880, at the meeting of the Pharmacopœia Convention in Washington, twenty-two were pharmacists and forty-two physicians, showing that it was a subject very important for physicians to consider, and not a subject for the pharmacist alone.

Dr. George M. Garland, of Boston, read a paper on

RAYNAUD'S DISEASE.

Gangrene in this form was not understood until some investigators, such as Virchow and others, gave as their theory that this symmetrical gangrene, or, as it was later called, Raynaud's disease, was due to certain disturbances of the trophic nerves. The patient has a numb or dead feeling in the part affected, and the temperature is reduced. Then there may come symmetric asphyxia, in which there is pain and blue color of the parts on both sides. In the third stage dry, mummified, or moist gangrene sets in, with great pain. Fatal cases occur. The theory is that it is a tropho-neurosis, but the theories vary widely. It is evident that similar conditions are produced

by different causes. Erythro-melalgia may be considered in this connection, it occurring symmetrically. The treatment is not satisfactory.

Dr. Chamberlain, of Mass., had seen a similar case, and had used morphia to deaden the pain and give the patient relief.

Dr. Herrick, of Cleveland, O., thought that in the two cases related, one an old man and one a child, it was not right to put them together as one type of disease.

Dr. Holden, of Vermont, had seen three cases, in persons otherwise healthy, and had used stimulation by having the hands plunged into hot and cold water alternately, with cure in three weeks.

Dr. Truax, of New York, objected to the nomenclature of the disease. He thought the profession should protest against having a disease named after a man.

Dr. J. V. Shoemaker, of Philadelphia, read a paper entitled

DIOSCOREA VILLOSA—WILD-YAM.

The root is used, it is pungent, pulverized with difficulty. A further analysis and a study of its physiological effect would be very interesting. A decoction, a tincture, and a fluid extract he had used. It acts as an emetic, diaphoretic, etc. It acts on the liver as in bilious colic; it affords great relief. Hepatic torpor is also quickly and promptly relieved by this remedy. In cirrhosis of the liver too much good must not be expected of any remedy, but dioscorea is of undoubted use here. After alcoholic excess, etc., it is of great benefit.

Dr. Jaggard, of Michigan, had used wild-yam in several cases and thought its effect was much like ipecac.

SECTION ON SURGERY AND ANATOMY.

First Day, Tuesday, June 25, 1889.

Dr. N. P. Dandridge, of Cincinnati, Chairman of the Section, read a paper on

SURGICAL INTERFERENCE IN FRACTURES OF THE SPINE.

The recent interest in the surgery of the spine dates from the removal of a tumor of the cord by Horsley, and the operation by Macewen for the relief of paralysis, in Pott's disease.

In applying the results to fracture, it must be remembered that, in cases of tumor, operation is the only method of treatment which promises any benefit. In Pott's disease paralytic symptoms often disappear, even after long continuance, and in one personal case, complete paraplegia lasting for more than three years and a half was finally relieved. Very often, however, the thickening of tissue making pressure on the cord, resembles permanence, a tumor growth, and removal by the knife offers the only prospect of relief. The result of trephining the spinal canal, in these cases, has given most brilliant results; recovery taking place in one case of Horsley's after six or seven years of paralysis, and in one of Macewen's after two years. The analogy of these cases and fracture must be applied with caution. In fracture the damage done to the cord is often immediate, and is not often due to continued pressure from narrowing the canal by displaced bone. Following fracture, however, we may have pressure produced by inflammatory products, which may assist in continuing the symptoms. In discussing the propriety of operation it is proper to consider the results obtained in fracture of the spine without operative interference. Burrill has shown that twenty-one per cent. survive, and one half of these make satisfactory recovery. It is apparent from these figures that a considerable number of cases are brought to a satisfactory termination, and in these the symptoms of paralysis, bedsores, and incontinence do not show any evidence of improvement for weeks after the injury.

In five cases of fracture of the dorsal spine under the writer's care, the plaster jacket was applied in three soon after the injury—in two with a satisfactory result and complete disappearance of paralysis. In the third, the recovery was only partial. In these cases the plaster jacket was applied by the hammock suspension, as suggested first by Mr. Davy. In one case suspension was employed five months after the fracture, and was followed by marked benefit. The fifth case was trephined, and the tenth, eleventh, and twelfth dorsal, and first lumbar laminæ removed at the end of five months, for the relief of complete paraplegia, cystitis, incontinence of urine and fæces, and extensive bedsores. No apparent immediate benefit followed the operation, but eight weeks later the cystitis had disappeared, some of the bedsores were entirely healed and all were better, and the general condition was improved. In fracture of the spine immediate operation is not indicated, as a considerable portion of cases recover under less dangerous methods of treatment. The continuance of symptoms is an indication for operation, as it has been conclusively shown that the relief of pressure, even after long continuance, may be followed by complete restoration.

CONCLUSIONS.

1. In fractures of the cervical vertebræ, there is indicated immediate reduction of any displacement by extension and manipulation under an anæsthetic, followed by continuous extension and immobilization.

2. In all fractures of the lumbar or dorsal spine, involving the bodies or the arches, reduction is effected, with or without the plaster jacket by the hammock suspension, preceded, if there is evident displacement, by extension under an anæsthetic.

3. When symptoms indicating injury of the cord persist without improvement, resection is indicated.

4. Immediate operation would be indicated when there is marked depression of the arches with symptoms of paralysis.

5. Long continuance of the symptoms is not in itself a contra-indication to operation.

6. We have, in suspension, the means of alleviating some of the sequelæ of fracture of the spine.

Dr. H. H. Smith, of Philadelphia, read a paper on

CONCUSSION OF THE SPINE IN ITS MEDICO-LEGAL ASPECTS.

The legal liability of corporations and capitalists for claims of pecuniary damages for injuries received by individuals through a claimed negligence, was established by the English Parliament, in 1846, and is known as Lord Campbell's Liability Act.

A refusal to pay often carries the claim into court, and the medical testimony often becomes the turning-point of the case. A medical expert should, therefore, endeavor to hold the scales so level that the preponderance of the medical facts may correctly incline the balance to the right side. The following questions were presented:

1. Can any force be so applied as to produce concussion of the spinal cord and its nerves?

2. How are the normal functions of the cord disturbed by such injuries?

3. What pathological changes on the cord are found as due to its injury or disease? After answering these questions, the following conclusions were drawn:

1. Concussion of the spinal cord is no longer doubtful, but may occur from any marked violence, there being nothing peculiar in the application of force to the body as the result of railway derailment or collision.

2. The pathological changes noted in the molecular structure of the cord, as the result of shaking, etc., when attended by paralysis in any degree, may be due to hemorrhagic effusions, softening, and localized or limited atrophy.

3. The possibility of pre-existing neurasthenia, hysteria, or fraud, should be carefully noted in forming a diagnosis.

4. The prognosis should be guarded, especially in cases claiming permanent disability, as recoveries or marked improvement in a few weeks are recorded, even after the occurrence of paralysis.

5. No physician should go into court and swear that a plaintiff has had a concussion of the spine or its nerves

unless he has proved the disturbance of the normal functions of the cord as shown in sensation or motion, or both, and that the symptoms appeared soon after the injury.

Dr. Herbert Judd, of Galesburg, Ill., following Dr. Smith, said: It is demanded by the honest business interests of the country, by cities, by transportation, mining, and manufacturing companies, and by all employers of laborers, that the subject of spinal concussion receive the most thorough attention at our hands. If we do not expose the cheats and frauds, and protect the deserving claimant, who can do so? That cities and corporations are robbed of vast sums of money yearly by malingerers, aided by ignorant or dishonest surgeons, we all know to be true. This subject has reached this disagreeable status: A person can claim to be injured in a collision of trains, or by other accident. No objective symptoms or signs can be discovered, nor, upon close examination, found. Nevertheless, such person never fails to find abundant medical testimony, and the assistance of friends, which, with the required legal talent, will be sufficient to successfully prosecute a suit. Especially is this true when the defendant is a corporation. Such cases can be, and are, based upon and carried to the end upon only a few vague subjective symptoms, every one of which depends alone upon the word of the claimant who seeks damages.

It is said, and it is probably true, that more people are injured every year by riding in carriages and by farm-work than by railroads, yet injuries that are pure accident, or injuries where a corporation of some character is not at fault, never result in concussion of the spinal cord. And where injuries occur through accident for which no liability can attach, we find no malingerers.

A number of interesting cases were then related in detail.

Dr. Charles C. Hunt, of Dixon, Ill., read a paper on

SUSPENSION AND EXTENSION IN THE TREATMENT OF SCIATICA.

The three cardinal points in the treatment of sciatica are rest, extension, and suspension. He cites five cases, picked at random from a list extending over a period of five years. Recovery took place in from two to six weeks in all. The apparatus used was the old Hodgen splint, which should be worn at least two weeks, and the adhesive straps left on two or three weeks longer, so that extension can be put on after the patient goes to bed nights, or in case of accident or over-exertion. The paper consists of a few interesting clinical facts, no pretension being made to discuss etiology, pathology, diagnosis, or general treatment. A cut of the apparatus, with description and method of applying it, accompanies the paper.

Dr. Maurice H. Richardson, of Boston, reported a series of

FIFTY-SEVEN OPERATIONS ON PERIPHERAL NERVES,

taken from the records of the Massachusetts General Hospital, of which twenty-eight had been performed by himself.

Thirty-five cases of neurectomy for neuralgia were reported very briefly. Most of these cases were affections of the trifacial nerve. The earliest cases of trifacial neuralgia were treated by section of the motor nerve. This was probably done with the idea that pain was caused by facial spasm. These operations were unsuccessful. In the operations of later years one can observe a constantly increasing thoroughness and severity. In the beginning there was only a subcutaneous section of the nerve, while at the present time as much of the nerve-trunk as possible is excised. In obstinate cases the nerve is divided at the foramen of exit from the skull. The result of these operations has been an almost invariable temporary success; the period of immunity from pain lasting from a few weeks to several years, while in some a permanent cure has followed. The length of the period of relief bears some relation to the amount of nerve removed.

Several cases of

BUCCAL NEURALGIA

were treated after the method of Zuckerkandl, the main trunk of the nerve having been divided as it emerges from the space between the coronoid process of the lower jaw and the insertion of the temporal muscle. Several methods of operating on the inferior dental nerve were described, the most important of which was the total evulsion of the nerve by trephining over both dental and mental foramena. In one case, after dividing the distal end at the mental foramen, the whole nerve was drawn out of the dental canal by an intrabuccal incision, owing to the great difficulty of this operation, and interference with articulation following it. In one case the writer had trephined the lower jaw through the space occupied by the third molar tooth. In several cases the periosteum of the floor of the orbit has been raised and the superior maxillary nerve divided in the spheno-maxillary fossa, and drawn out of the infraorbital foramen; the distal filaments being twisted out of the tissues over clamp-forceps. This method seems preferable to Carnochan's operation of reaching Meckel's ganglion by going through the antrum. One of these cases was fatal.

Neuralgia treated by nerve-stretching, of which five were reported, all for sciatica, were, with one exception, failures. The experience of others, however, offers sufficient encouragement in obstinate cases. The experiments of the writer on the cadaver show that great force is necessary to produce any traction whatever upon the spinal cord. In some cases the nerve ruptures outside the pelvis, while in others it gives way at the intervertebral foramena. Nerve stretching as a means of affording relief, except in nerves containing important motor fibres, has little to commend it. Stretching should be combined with resection in all cases where the latter operation is performed.

Four cases of

MUSCULAR SPASM

had been treated by nerve-stretching. Of these, one was of the facial, two of the spinal accessory, and one of the lower intercostals. Temporary relief followed in the case of the facial spasm. The others were failures.

Two cases of spasmodic wry-neck had been treated by the writer by excision of a portion of the spinal accessory nerve. This method produced relaxation of the muscles and cessation of spasm. The best incision to reach the nerve is along the anterior border of the sterno-mastoid, the centre of which should be an inch and a half from the mastoid process. In the two cases reported it was reached through an incision an inch long.

Seven cases of suture of the nerves of the upper extremity were reported, in all of which, with one exception, there was more or less perfect restoration of function. An inch and a half of loss of nerve-substance can be made up by stretching. More extensive separation of the ends requires interposition of some connecting link, the best of which is catgut (*suture à distance*). The possibility of immediate restoration of sensation and motion was doubted; it not having occurred in the writer's experience. One must not be discouraged if there are no signs of improvement for a long time. In one case of secondary resection of the musculo-spiral nerve there was no evidence of motor restoration for three months, though the case resulted in a perfect cure.

Two cases of pain and of

PARALYSIS FROM PRESSURE

had been treated by incision and removal of exostoses and tumor, with permanent relief. In one, wrist-drop had been cured by relieving the musculo-spiral from compression between the aponeurosis of the triceps and an exostosis of the humerus.

Dr. W. O. Roberts, of Louisville, Ky., narrated three cases upon which he had operated during the last eighteen

months, for removal of the inferior dental nerve. The dental engine, with burr, was used in place of the trephine.

In the first two cases, incision was made through the soft parts down to the bone, along the outer border of the jaw along its entire length. The burr was applied at the mental foramen and carried along the whole length of the canal. After opening the canal the whole nerve was lifted out and removed entire.

In the last case (the third), an old lady, with a large mouth and the bone very much atrophied, an incision was made along the whole length of the jaw from the inner side of the mouth, and the burr of the dental engine run over the covering of the canal. On opening the canal, there was free hemorrhage, which was relieved in a short time by pressure.

The first case was lost sight of after four months. Up to that time there was no relapse. In the second case, operated on a year ago, there has been no return of pain. The third case was operated on ten days ago, and is too recent to judge of the ultimate result. It is more difficult to operate from the inside than from the outside of the mouth, but it is to be preferred when it can be done, for the sake of leaving no scar.

SECOND DAY, WEDNESDAY, JUNE 26TH.

DR. CHAS. B. PORTER, of Boston, read a paper on

EXSTROVERSION OF THE BLADDER.

The subject of the communication was the report of operations of two cases of exstroversion of the bladder —a congenital deformity in which the bladder, with mucous surface exposed, protrudes, hernia-like, in the lower hypogastric region. Its anterior wall and corresponding portion of the abdominal parietes are wanting, and usually the symphysis pubis. The urine dribbles from the ureters, or is ejaculated on coughing or sneezing. Its constant contact excoriates the skin of the genitals and thighs, and makes its possessor miserable, and the attendant foul urinous odor an object of repugnance to those about. The other parts of genito-urinary system are usually present in a more or less developed state. It will be interesting to spend a few moments in considering the evolution, so to speak, of operative interference to remedy this deformity. So far as I can ascertain, no operation for exstrophy was performed till the last half of the present century, when Mr. Lloyd, of St. Bartholomew's, in 1851, made an attempt to divert the passage of the urine into the rectum by passing a seton from the bladder through into the rectum, intending subsequently, after the fistulous tract was established, to close the gap in the abdominal wall, refreshing its edges, and uniting them by suture. His patient died on the fifth day, from peritonitis. Since Lloyd's unsuccessful attempt to establish communication with the rectum this has been accomplished by Simon. Holmes, in order to avoid a wound in the peritoneum, endeavored to establish a tunnel through the perineum with communication of the ureters with the rectum. Thomas Smith diverted each ureter into the colon of the corresponding side by successive operations. His patient died after the second. Until 1853 no successful attempt had been made to cover the exposed bladder by flaps, when, almost synchronously, Roux, Richard, Pancoast, and Ayers each performed a successful operation by transplantation of flaps of skin from the adjacent parts. In the adult, and especially in the male, the introverted skin grows its hairs, and the deposition upon them of the salts of the urine forms concretions that are analogous to stone in the bladder and produce similar symptoms. To reduce this reservoir to a minimum Dr. Henry J. Bigelow, of Boston, in 1876 dissected the mucous membrane from the exposed surface above a line drawn transversely across the ureters and turned a flap of skin onto the denuded surface, which united. The part below this line was covered by another operation. Trendelenburg, of Bonn, reported to the Sixteenth Congress of German Surgeons a number of cases by a new method.

In children, and he limits the age to those under six years, he performed section of the sacro-iliac synchondroses on both sides, and, by continued pressure, kept up by special apparatus, lessened the pubic hiatus to one centimetre. The bringing together of the refreshed edges of the bladder has been attempted twice, once unsuccessfully by a Strasbourg surgeon, and once successfully, in 1844, by Dr. Hal C. Wyman, of Detroit.

CHOICE OF OPERATION.

With regard to the choice of operation, the speaker thought that age and extent of the cleft must determine. Up to the present time no operation has attained continence of urine. The results of diverting the urine into the intestine are not encouraging. Diverting the urine to a central point in the abdominal wall does not commend itself, although no deaths had followed the four cases which the speaker had been able to collect. Trendelenburg has up to the present time achieved no more than the method by flaps, and any surgeon would hesitate to submit his own child to bilateral section of the sacro-iliac synchondroses as a preparatory step to the closure of the vesical cleft. In an infant or young child Wyman's method is, in suitable cases, the best. It is practically Trendelenburg's, minus the objectionable feature of the sacro-iliac symphyses. The method by flaps is adapted to both sexes and all ages. The surgeon before the operation should inform himself as to the condition of the kidneys, and constantly keep in mind the main result for which he is striving, namely, a free drainage of the urine; for, otherwise, the ordinary results from obstruction generally follow. These are dilatation of the ureters and destruction of the kidneys. None of the accompanying malformations contraindicate the operation. The development of prepuce and scrotum in the male, and the labia majora and minora in the female, furnishes the operator abundant material for the display of his ingenuity in arranging flaps.

All the general rules of plastic surgery hold in these operations. The flaps must be about one-third larger than the gap to be filled.

They must be arranged in such a manner as to furnish to the pedicles an abundant supply of blood.

During delays in the operation they should be covered with hot towels wet in an antiseptic solution.

They must be handled as little as possible, and rarely with forceps.

Any dragging on the pedicle endangers the vitality of the flap.

All bleeding must be arrested before the flaps are adjusted in position.

Light and gentle compression prevents any oozing between them.

The operation completed, they should be kept for many hours under moist, hot, antiseptic dressings.

Perfect antisepsis should be maintained throughout.

Two cases were reported, one of which was shown.

DR. DUDLEY P. ALLEN, of Cleveland, O., read a paper on

LITHOLAPAXY IN CHILDREN,

in which he said that this operation had now come to occupy a recognized position among the operations for stone upon children, and had achieved a great success.

He compared it with the operation of lateral suprapubic lithotomy, and pointed out the comparative merits of each operation. He also read letters from G. Buxton Brown, of London; Guyon, of Paris; Kerr, of Canton, China; and Petersen, of Kiel, Germany. Brown and Guyon are favorable to litholapaxy in children, under proper conditions. Kerr and Petersen had not attempted litholapaxy in children, always cutting; Petersen wrote especially of suprapubic lithotomy in cases when it was indicated; and Kerr, of the advantages of median lithotomy in small stones.

Dr. Allen's conclusions were that litholapaxy in children is adapted especially to medium and small stones, and that its especial advantages are :

1. The absence of a cutting operation, for dread of which patients frequently delay operation until the stones have reached a large size.

2. The short convalescence, averaging but a few days.

3. The absence of the offensive discharge of urine into the patient's bed, with its disagreeable and sometimes serious consequences. He also spoke of the absence of any risk to the reproductive apparatus, and the fact that boys' bladders were less liable to be diseased than adults', and consequently better able to withstand operation. He advocated treatment of the cystitis which accompanies stone by washing the bladder for a time after the operation, should this be indicated, and expressed the opinion that this would secure as beneficial results to the bladder as drainage by the cutting operation. He thought that, even if stone returned more frequently after litholapaxy than after lithotomy (as was not proved to be the case), this might be prevented by washing the bladder until its condition had become healthy, and should a stone return a second operation by litholapaxy would be easier than the first from the increase in size of the urethra with the age of the patient. In concluding his remarks he showed various instruments and stones removed by the operation.

Dr. W. T. Briggs, of Nashville, Tenn., read a paper on

THE CHOICE OF OPERATION FOR THE REMOVAL OF VESICAL CALCULI IN THE MALE.

There is no *best* operation for the extraction of urinary calculi. Every case of stone has its special indications, and the best results will be attained by the surgeon who has a thoroughly practical knowledge of all plans of operating, and who appreciates the paramount importance of selecting the operation best adapted to the case under consideration.

The data from which a choice is determined are :

1. The age of the patient.
2. Size and consistence of the stone.
3. The recurrence of the stone.
4. Condition of the urinary apparatus.
5. The results of the different methods.

It is almost universally conceded that in children under sixteen years of age lithotomy is one of the most successful of the major operations. The writer had operated on seventy-one children by the medio-bilateral method, and all fully recovered.

The writer thinks it may be safely concluded that in children under sixteen years of age the cutting method should be chosen, as the safer and better method of removing vesical calculi.

After puberty, and even in advanced age, crushing is the operation *par excellence*, and when the environments of the case have been favorable it has proven eminently successful.

The various methods of operation were discussed.

The medio-bilateral method is the choice of the writer, for the following reasons :

1. That it opens up the shortest and most direct route to the bladder, passing in a straight line from one-third of an inch anterior to the verge of the anus to the neck of the bladder; it facilitates the introduction of instruments and the extraction of the calculi.

2. It divides parts of the least importance. The incision following the median line does not encounter any structure of importance, nor does the slight bilateral section of the deeper parts do violence to tissues of vital consequence.

The following deductions were drawn :

1. No operation is adapted to all cases.

2. Litholapaxy is incomparably superior to lithotrity, and should always be practised in selected cases.

3. The suprapubic should be chosen for extraction of very large and hard stones.

4. The medio-bilateral should be chosen in all other cases.

In adult life the death-rates alter somewhat in favor of litholapaxy. As the prostate and urethra enlarge, and the parts about the neck of the bladder become more vascular, the danger incident to cutting through them increases. On the other hand, the increase in the size of the parts makes the performance of litholapaxy comparatively easy and safe. In old age the rates of mortality are overwhelmingly in favor of litholapaxy. While the dangers attending all the cutting operations have increased very greatly, the mortality after crushing is very little higher than it was earlier in life.

In childhood, it would seem wise to use litholapaxy for all small stones or stones of moderate size, and for stones of larger than this to do lateral lithotomy, except when they are very large, and then suprapubic cystotomy is to be resorted to.

In adults we are led to regard litholapaxy as the operation of choice for stone-removal. In old age the same indications are to be followed as in the adult, except that it is to be remembered that perineal incisions are especially dangerous in old men, and not to be undertaken for the removal of stone without urgent reasons.

These two papers were jointly discussed by Drs. Gouley, Sir James Grant, Tremaine, and Pancoast.

Dr. A. T. Cabot, of Boston, read a paper on

THE CHOICE OF OPERATION FOR STONE IN THE BLADDER.

In his opinion, we have in litholapaxy a choice for the removal of most stones. While this is the rule, there are exceptions to it, and the varying conditions surrounding stones in the bladder will now and then lead us to choose some other operation for their safest removal. In modern surgery the test of merit is looked for in results. No operation, however brilliant, can claim superiority over rival methods if its death-rate is higher than theirs. The best operation is the one that saves the most patients, unless some serious interference with bodily function more than counterbalances the gain in safety.

In children, judging from the results of mortality, there is little to choose between lateral lithotomy and litholapaxy. Suprapubic lithotomy is more dangerous.

Dr. Robert T. Morris, of New York, read a paper entitled

WHAT DRESSING SHALL LIE NEXT THE WOUND?

Vaseline or oil spread upon any textile fabric represents the worst type of dressing, because the unguent mingles with the discharges and retards organization; because the textile fabric entangles new epithelium-cells and connective-tissue cells, and because there is nothing in the dressing to prevent fermentation and wound-infection. Lint and cotton are even worse than textile fabrics.

The cerates spread upon textile fabrics are one point better, in that new epithelium and connective-tissue cells are not entangled in the mesh.

Balsams spread upon textile fabrics, or upon lint or cotton, are better than vaseline or cerate, because they may limit fermentation.

There are only two perfect types of dressing. The iodoform covering for small wounds represents one of these. Iodoform forms a thin, firm coagulum with lymph, and this is not easily attacked by micro-organisms. Beneath this coagulum the processes of repair go on smoothly in small wounds, even when a certain number of microbes are at work, because the iodoform neutralizes the ptomaïnes.

The other perfect dressing is the one suitable for larger wounds, and it possesses the following properties : First, smoothness and impenetrability to new epithelium and connective-tissue cells (Lister's protective oiled silk). Second, a bulky mass which is highly absorptive, to draw serum away from the wound, and to make it too dry for microbe food; and this dressing is charged with antiseptics to destroy micro-organisms (bichloride cotton or gauze).

ELECTION OF OFFICERS.

Dr. B. A. Watson, of Jersey City, was elected President, and Dr. William B. Deaver, of Philadelphia, Secretary.

Dr. J. Collins Warren, of Boston, read a paper on

THE MANAGEMENT AND TREATMENT OF LARGE HERNIÆ.

The very large herniæ appear to have a *raison d'être* in each case, that is, the patient usually suffers from some form of disability, which prevents him or her from exercising that control over a hernial tumor which an able-bodied and intelligent person is usually capable of doing. In a large number of cases obesity is a predisposing cause, especially in hernia in women. The type of man usually afflicted with a large scrotal hernia is twofold. Either he is a large, middle-aged business man, so engaged with his work, or of so callous a temperament, as to have neglected his disease until driven to treatment by fear of permanent disability; or, he is an old and feeble individual, or so obtuse as to be unable to manipulate the part so as to effect a reduction, or with sufficient intelligence to apply and keep in place a truss. Finally, we have children with congenital herniæ, whose position in the social scale is so lowly that the little patient has never been able to receive proper care. The cases narrated represented fairly well each type of this affection. No special plan of treatment has been adapted to them all, but each case has received such treatment as the special conditions governing it seemed to call for. Nine cases were related in detail. In none of these cases was a radical cure attained, but in all the patient has been satisfied with the result of treatment.

Dr. Henry O. Marcy, of Boston, read a paper on

THE RADICAL CURE OF HERNIÆ BY THE USE OF THE BURIED ANIMAL SUTURE.

Dr. Marcy gave a brief history of fourteen cases operated on within eight months, and since they embraced all the varieties of herniæ, they comprised of themselves a study of marked interest, and illustrated the author's methods of operating. The specimens of the hernial sac, and, in a few instances, contents, were of great value. They were exhibited especially to show the changes which take place in the peritoneal sac, and teach that at least in cases of old, large herniæ, it has become so intimately blended with the surrounding connective tissue, and is so deformed and devitalized as to be considered distinctively pathological and utterly devoid of value as an aid in the restoration of the parts. When thus changed it is clearly the duty of the surgeon to remove it. Dr. Marcy dissects the sac quite within the ring, making the neck tense by traction, and then with the double continuous suture, rendered possible by the eye of the needle being placed near the point, and known in surgery as the author's stitch, sews in an even seam in the line of the oblique opening across the mouth, and resects. The peritoneum thus reformed is carried quite within the ring, and in old, large inguinal herniæ the inner ring is closed from below upward by the double suture quite upon the cord. In this way the obliquity of the canal is restored, a step which Dr. Marcy emphasizes as of the first importance.

The pillars of the refreshened ring are now brought into apposition by the double continuous suture quite to the exit of the cord at the lower margin of the external ring. The external tissues are approximated in the same way by a layer of continuous buried sutures, and finally the skin is held in juxtaposition by a running blind stitch taken from side to side through the deeper layer of the skin. In this manner not only is the canal restored, but the tissues are held in close relation, bleeding rendered out of the question, and all pockets avoided for an accumulation of any secretion. On this account drainage is unnecessary, and the wound, which at every step has been under the protection of irrigation with mercuric solution, is at once dried, and sealed with iodoform collodion. Aseptic pain rarely is sufficiently severe to require opiates. The tissues are agglutinated without swelling, or even tenderness. If done as Dr. Marcy insists all operative wounds should be made, only under more aseptic precautions, the procedures which at first seem heroic and even dangerous are really safe, and to a good anatomist and practised surgeon, simple. This general method is advised for the different varieties of herniæ, and has given, in the experience of Dr. Marcy, most excellent results. He has now operated about one hundred times for the cure of herniæ, and a recent examination, as far as possible to trace results, gives about ninety per cent. of permanent cures. In no case has the danger line appeared to have been approached, except in strangulated cases, where the integrity of the intestine was involved. The author said that he believed he was the first American pupil of Mr. Lister, and soon after his return from Edinburgh he operated, inclosing the ring with catgut, because the patient was afflicted with a severe cough. The cure was perfect and other cases soon followed. Then a long and careful comparative histological study of animal sutures incorporated into the living tissues, followed with the demonstration that they were replaced by vitalized connective-tissue cells. His first studies were in 1870, and the priority of his method of operation has never been questioned. The importance of such a discovery is apparent in its general application to surgery, but nowhere of greater value than in herniæ. After a careful study of all the varieties of animal sutures, Dr. Marcy is satisfied that the tendon from the tail of the kangaroo is by far the best. The author said that he recently published a general treatise upon herniæ, and this paper embodied his more recent experiences.

Dr. Joseph S. Warren, of Boston, in discussing the paper of Dr. Marcy said: "I am aware of the claims for animal ligatures, but I have always feared their advantages might be too great, and the absorption claimed for them might be premature. In my own operations I use braided silk, and feel secure when the parts are approximated, they will stay so until united." Dr. Warren's peculiar way of stitching the ring was then described, and the needles which he uses shown.

Dr. John B. Deaver, of Philadelphia, read a paper on

THE RADICAL CURE OF HERNIA.

The operations of Macewen, Baker, Banks, McBurney, and others were described. The method which the author usually employs is Baker's, modified only in the introduction of the sutures after the manner of Macewen for closing the canal. He uses antiseptic silk sutures, and a few strands of chromicized catgut placed beneath the superficial set of sutures. The operation that he has done most recently is a modification of McBurney's, differing from it only in that the fundus of the sac is left *in situ*. This, of all operations, he considers the most rational and the least likely to be followed by a return of the hernia. This is the course also pursued in femoral hernia.

Dr. Charles W. Dulles, of Philadelphia, read a paper on

PROPERITONEAL HERNIA.

The subject of properitoneal hernia is so little known in the country that I believe there have been but three cases with this title recorded by American surgeons. One by the writer in 1886, the second by Dr. Hartley, of New York, and the third by Dr. Torrey, of Brooklyn. In a general way a properitoneal hernia may be said to be one which occupies an abnormal position within the abdominal or pelvic wall in front of the peritoneum. Lunenburg has suggested that the term præ-peritoneal would be more exact. A true properitoneal hernia lies between the peritoneum and the overlying mass of muscles, or when pelvic, the bones. There is also a form of hernia which occupies a position between the planes of the

abdominal muscles, which may be called "intermuscular," and another which lies outside of them and just beneath the skin and superficial fascia. The history of cases of this sort seems to be that they are for the most part originally inguinal hernias, and often accompanied by an undescended testicle. After occupying the inguinal canal for a certain time, the obstruction offered by the incarcerated testicle, or sometimes by a truss, forces the protrusion, under a strain, out of the canal and into the loose tissues between the peritoneum and the muscles, or between the muscles themselves, or between the whole mass of muscles and the skin and superficial fascia. They usually occupy a position above and parallel to Poupart's ligament, and stimulate enlargement by hydrocele of the spermatic cord. They are sometimes so large that they overlap Poupart's ligament and hang down over the thigh. They often extend upward and outward as far as the anterior superior spine of the ilium. The treatment is usually by cutting operation. I have found the record of a case which was successfully treated by taxis, and my investigations have led me to the belief that this is the most dangerous way to treat it.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

FIRST DAY, TUESDAY, JUNE 25TH.

W. H. WATHEN, M.D., CHAIRMAN.

DR. H. R. STORER, of Newport, read on the subject,

BENJAMIN RUSH AS AN OBSTETRICIAN.

In studying medical numismatics he had been struck with the importance of the work of Benjamin Rush in the department of obstetrics. Fifty years ago the idea of the induction of anæsthesia in obstetrics was

AN AMERICAN IDEA

in the mind of Rush, and he, after observing a painless delivery while the mother was in an epileptic fit, and another while the mother was intoxicated, prophesied the finding of a drug which would relieve the pains of childbirth. The writer brought this subject up before this section because he thought Rush a man who deserved well of the section on obstetrics, especially as an effort was now being made to raise him a monument. On resolution the paper was referred to the general session when the subject came up.

BORACIC ACID IN GYNÆCIC PRACTICE

was the subject of a paper by DR. W. W. POTTER, of Buffalo, N. Y. The doctor was first brought to the use of boracic acid by the fact that iodoform in him always caused a very troublesome dermatitis. He found boracic acid valuable when the medication was required to remain longer in the vagina than it was possible for tampons to remain on account of the decomposition. He then described minutely his method of applying the remedy, which consisted of an injection, a drying of the vagina, the application of the boracic acid with alternating layers of cotton. He, in some cases, allowed this dressing to remain a week, and thought once a week often enough for these applications. He has had good results with boracic acid after plastic operations. In these cases he leaves a rope of borated cotton hanging from the os over the perineum.

He considered boracic acid a remedy of great value in sterility due to acrid secretion, which destroys the fecundating power of the sperm. It is one of the best powders to render operative wounds in the genital tract aseptic. Boracic acid is suited to many gynæcic uses where an antiseptic is required. It can claim superiority over the vaginal tamponnement by reason of odorless, colorless, non-irritant chemical properties; these admitting of its frequent liberal and prolonged treatment.

DR. WILLIAM H. TAYLOR, of Cincinnati, reported

A CASE OF ECTOPIC GESTATION SUCCESSFULLY TREATED BY GALVANISM.

The great practical importance of extra-uterine gestation, and the prominence it now holds as a topic of discussion, he thought, justified his contribution. The diagnosis being difficult, the first essential interest centres about this point. The doctor then gave a concise review of the latest published utterances on the subject of diagnosis and symptomatology. His case was then reported to show how clearly it followed out the symptoms, and read in brief, as follows:

Mrs. W—— has borne three children, the last two and a half years ago, since which time menstruation has been regular and normal till recently, and she has been in good health. She menstruated in September, but missed her October menstruation entirely. She noticed abnormal desires for food, which led her to suspect pregnancy. October 30th she had a slight discharge of mucus tinged with blood, which continued till November 15th. The amount and character varied; when the flow was slight, it was dark and offensive. She grew better till November 29th, when, without obvious cause, she was seized with intense pain in the lower part of the abdomen, which compelled her to remain unmoved in a semi-flexed position till carried to her bed. She vomited violently, had intermittent pain with a free flow of blood. The phenomena of shock were so severe that for twelve hours death seemed imminent. Her highest temperature was 99 degrees. In four days she was much improved in all respects, and the flow of blood had ceased. December 13th she discharged what her physician said was fœtal membranes, since which she has lost no blood.

December 20th she had a second attack of violent pain, not so severe or protracted as the first, with no flow of blood. Since the beginning she has been subject to brief severe pains in the iliac region, produced by any exertion.

Her physician suspected extra-uterine pregnancy, and Dr. Taylor saw her the first time January 3, 1889. She was mentally and physically depressed, and sure her abdomen was growing larger. She had no mammary signs of pregnancy, though perversion of appetite continued. Abdomen tender to the touch, pain increased by deep pressure, no tumor detected by palpation, auscultation negative; vaginal examination showed the uterus deflected to the left, os patulous, not much enlarged, but, as the introduction of the sound caused much pain, the cavity was not explored. To the right of the uterus and apparently loosely connected with it, was a firm, irregular oval mass the size of the fist, slightly movable and not very tender, with a feeling of pressure on the rectum. From the history given, this tumor had probably grown during the past few weeks.

During the ensuing two weeks the continuous current was applied six times by means of a ball electrode in the vagina, and twice with sponge on surface of abdomen. Vesication occurred, and a large wire gauze was substituted. From eight to twenty cells of a Waite & Bartlett's battery were used, and under anæsthesia the current was carried to one hundred and twenty-five milliampères. A very remarkable effect mentioned by the patient was, that from the commencement of her sickness her extremities had constantly been cold and clammy, but from the first application of the battery they had grown warm.

She left the city January 19th, at which time her general health was much improved and her normal appetite had returned.

February 25th.—The tumor has decreased, not painful, uterus somewhat retroverted.

April 11th.—Has gained in weight, no pain, menstruation normal again.

All are aware of the diversity of opinion that exists as to the relative value of electricity and laparotomy in the early treatment of ectopic gestation. Granting the cor-

rectness of the diagnosis, he felt warranted in claiming success by the former treatment in his case.

THE CHAIRMAN then delivered his address, entitled,

THE PATHOLOGY OF ECTOPIC PREGNANCY AND PELVIC HÆMATOCELE.

The speaker considered of no practical value everything written on the subject of ectopic pregnancy prior to the year 1880, and passed it by. He considered that the ovum was never impregnated in the uterine cavity, and thought that the conjugation of the male and female elements must take place before, or just after, the ovum enters the tube. Ectopic pregnancy is always primarily tubal, with the possible exception of ovarian pregnancy. Abdominal pregnancy cannot occur except as a result of primary or secondary rupture, and if the villous or placental attachments are destroyed the ovum immediately dies, because it cannot form secondary attachment to other structures. If in rupture into the peritoneal cavity the ovum retains villous or placental attachments, it may be possible under certain conditions for the pregnancy to continue, though not probable. If the amnion is ruptured in the early months the embryo or fœtus will die. So-called interstitial pregnancy does not always, though usually, rupture into the peritoneal cavity. If we define pelvic hæmatocele as an encysted or confined tumor formed of blood, then intra-peritoneal hæmatocele is not possible. Then followed an extensive argument upholding these propositions advanced concerning ectopic pregnancy.

The intimate relations existing between pelvic hæmatocele and ectopic pregnancy was his reason for considering these two subjects together in his address. Nearly every author who has written on this teaches that blood may accumulate in the peritoneal cavity, and become rapidly encysted and fixed by the effusion of a layer of lymph exudations. The author did not adhere to this belief. He thought it impossible. If in suppuration the fluctuation can be distinguished through the vagina, it is best to enter the tumor through the vaginal vault; but if no fluctuation can be discovered, but is felt above the pelvis, laparotomy should be done.

SECOND DAY, WEDNESDAY, JUNE 26TH.

ELECTION OF OFFICERS

resulted as follows: For Chairman, Dr. W. W. Potter, of Buffalo, N. Y.; for Secretary, Dr. Joseph Hoffmann, of Philadelphia.

DR. HENRY O. MARCY, of Boston, contributed a paper on

CHRONIC INVERSION OF THE UTERUS,

with illustrations, demonstrating a new method for its cure. After sketching somewhat briefly the history of chronic inversion of the uterus and its etiology, Dr. Marcy discussed more fully the pathological changes that ensue. These were illustrated by a considerable number of crayon sketches from the monograph of Crosse, of more than a century ago, from McClintock, Martin, Barnes, and others. Until 1858, when the late Dr. James P. White, of Buffalo, first published his monograph upon "Chronic Inversion of the Uterus," and its reposition by continued elastic pressure combined with taxis, no systematic effort for the cure of this distressing accident had been advocated. Although cases of reposition were on record, the profession had considered them as

ACCIDENTAL CURIOSITIES.

The methods of Tyler Smith, Wing, Barnes, Thomas, and Aveling of reduction by continued elastic force were analyzed, and shown, in the opinion of the writer, to be at the most modifications of Dr. White's original method, and often of doubtful value. No new principle being involved, undoubtedly to Dr. White and to America should be accredited the modern operation by which, at the least, a large proportion of cases of chronic inversion of the uterus can be safely restored, giving to the patient original health and vigor. Dr. Marcy somewhat critically reviewed the experience of Dr. Thomas and his followers, in first

PERFORMING LAPAROTOMY IN ORDER TO DILATE THE CERVICAL CONSTRICTION,

and thus aid in the reposition of the organ. This he admired as an evidence of the brilliant originality and fertile genius of this distinguished author, yet he could not help the consideration if it was based upon sound mechanical and physiological law. This seemed especially to be called in question by the analysis of the recent experiences of Dr. Mundé, of New York, where, after repeated dilatation to the uttermost, the cervical closure immediately followed, like the grip of a vice, which rendered every effort at reposition abortive. Again, although no harm is reported to have been occasioned by the severe pressure to which the Fallopian tubes are necessarily subjected, or mention made of the same by any author, it seems hardly possible to consider that these important organs can escape serious damage by such manipulation.

Twelve years ago, after a careful study of the subject, Dr. Marcy believed that all the above methods were essentially faulty, in that the fixation of the counter-opposing force was uncertain and doubtful. By the method of Dr. White counter-pressure over the abdomen was, in a measure, relied upon, but the method of all the other authors for the application of continuous elastic force, often applied for days together, was only the vaginal attachment of the cervix and pressure upon the neighboring organs. It seemed to him both simple and rational to utilize a single force in the power applied at the same time continuously upon both cervix and fundus, and in this way to convert the constricting force into a power to aid still further in its reduction. To this end he passed long ligatures of coarse silk deeply through the cervical tissues which he determined were possessed of ample resisting power. The perfected instrument for the reduction of the inverted uterus which was exhibited by Dr. Marcy seems simple and yet possessed of sufficient power. The distal end consists of a cup-shaped extremity for the reception of the fundus. The deep cervical ligatures, four in number, are attached to a movable sleeve adjusted upon the shaft of the instrument. By means of a screw in the handle pressure is brought to bear upon a concealed spring, and the force applied is at once determined upon a graduated scale, showing the amount of pressure. Dr. Marcy has but one case to report, which came under his observation within the year. Three months after delivery, a prolonged effort at taxis proved unavailing. By the method above described Dr. Marcy completely

RESTORED THE UTERUS IN TWENTY-SIX MINUTES,

under a maximum force of eight pounds. The sutures were easy in application, they held perfectly, and the operation was conducted throughout under irrigation, and afterward the vagina was lightly tamponed with iodoform cotton. The patient made a good recovery and continues well.

DR. A. P. CLARK, of Cambridge, Mass., commended the instrument of Dr. Marcy and his method of treatment.

DR. CLEVELAND, of New York, had seen but one case in fifteen years' connection with the Woman's Hospital. This case had a fibroid, after the removal of which reposition was rather easily made. He thought the instrument presented to-day superior to any he had seen.

DR. MONTGOMERY read a paper on

THE INDICATIONS FOR, AND LIMITATIONS OF, THE OPERATION FOR THE REMOVAL OF THE APPENDAGES,

urging the importance of their more accurate determination. The operation was introduced on three lines of indications: 1. To bring about the menopause in what

are known as the neuroses. 2. For the relief of symptoms due to pathological changes in the tubes and ovaries. 3. To establish the menopause in grave and threatening disease in the uterus. The aims of the operation as here expressed are legitimate when the indications are correctly interpreted. The indications may be divided into physiological and pathological: the former comprising operations done to establish the menopause, without reference to the pathological conditions present; the latter, primarily, for the removal of diseased organs, and may be partial or complete. The operation is justifiable in mania and epilepsy, when they can be closely associated in origin, or subsequent occurrence, with the menstrual function. It affords no relief in nymphomania, as the ovaries and tubes do not govern the sexual appetite, nor the power to gratify it. In hysteria it should be a *dernier ressort*, and then performed only after the patient has been fully informed of the influence it is likely to exert upon her future life. Its value in uterine myomata cannot be questioned, but the exceptional cases in which the flow is not arrested make it advisable, when feasible, to do vaginal hysterectomy.

Suppurative inflammation of ovary or tube is a positive and imperative indication. The frequency of the association of this with peri- and para-metritis makes it good practice to advise exploratory incision, with a view to removal of the offending organs in recurring attacks of either of the latter diseases.

Chronic inflammation of the tubes and ovaries is not necessarily an indication for operation. Polk and Imlach have done good work by demonstrating that many cases can be restored to health by separating adhesions and shortening the broad ligaments.

In conclusion, he urged that: 1. The operation for the removal of the appendages should be promptly performed in every case in which it is evident that relief cannot be otherwise obtained. 2. It should be considered a *dernier ressort* where there is a hopeful prospect of restoration to health by less dangerous methods, or without the sacrifice of the reproductive function. 3. Its consideration should be dismissed in every case capable of restoration to health by other plans of treatment.

Dr. Joseph Price, of Philadelphia, reported

A SERIES OF FIVE HUNDRED CASES OF CONFINEMENTS IN A MATERNITY HOSPITAL,

in which he gave the minutiæ of the treatment in a maternity hospital in Philadelphia with which he is connected. The treatment was after the highest and most approved method of cleanliness. He said the talk a few years ago was to abolish the lying-in hospitals on account of their terrible mortality. The tables are now turned, and the greater mortality is in the private practice. He wished to invite a discussion which would lead to more refinement in the technique of the treatment of labor.

Dr. Thomas Opie, of Baltimore, had visited the maternity spoken of and found it unique. He had great hopes for the future in this line.

Dr. Hurst, of Philadelphia, considered the plumbing of great importance. In an infirmary where he practised he had the closets put in towers, where the ventilation was excellent, and had within twenty-four hours a fall of temperature. He had found the mortality to be very great in tenement-houses where the plumbing was at fault.

Dr. W. T. Lusk, of New York, thought that the practitioner should hold himself responsible for the plumbing of the house in which he delivered patients.

Dr. Henry D. Frey, of Washington, D. C., read a paper on the subject of

THE APPLICATION OF THE FORCEPS TO TRANSVERSE AND OBLIQUE POSITIONS OF THE HEAD; DESCRIPTION OF A NEW FORCEPS.

He had sent circular letters addressed to the teachers of obstetrics in the United States, asking their practice in these conditions and the kinds of instruments they used. He gave their replies in a tabulated form. He thought the obstetrician should not content himself with one form of instrument, but be expert with several, so as to be able to use them as occasion demands.

Dr. William S. Stewart, of Philadelphia, read a paper entitled

WHEN SHOULD THE OBSTETRIC FORCEPS BE USED, AND WHAT FORM OF INSTRUMENT IS REQUIRED?

They should never be used to save time, no difference how busy the practitioner was, nor to satisfy nervous women or fidgety nurses. We should use the form of forceps best fitted to the particular case. He presented a pair of his make which he had used in a number of cases with good success. In these either blade can be introduced first, the child is not disfigured, and they do not slip.

Dr. Joseph Taber Johnson, of Washington, D. C., thought that woman in childbirth should be given all the skill extant, and recited the glories won by the forceps in the lying-in chamber.

Dr. Theophilus Parvin, of Philadelphia, considered this the revival of an old instrument which will also become an old instrument, and be revived by someone else. He thought it dangerous, that it would crush the child's head. It was an ingenious, complicated instrument, but we want simplicity. The power is too far remote from resistance, for the nearer you can get a horse to the load he pulls, the better he will pull.

Dr. Joseph Price, of Philadelphia, looked upon the forceps of Dr. Stewart as dangerous instruments.

Dr. Thomas Opie, of Baltimore, read a paper on

THE KINSHIP OF OBSTETRICS AND GYNECOLOGY.

He reviewed the history of obstetrics from the earliest times, and always found it closely allied to the diseases of women. He found obstetrics and gynecology bound together with hooks, forceps, and specula of steel. A few years ago the opinion was that lying-in hospitals should be abolished. Now they challenge private practitioners with their results. Gynecology has grown out of obstetrics—an obstetric development; they are separated but not divorced, they interdigitate. The gynecologist should know obstetrics, and the obstetrician should be a good gynecologist. The very nature of the gynecologist insists that he should be first an obstetrician. To know the abnormal he should first know the normal. United they stand like Siamese twins. To separate them would inflict irreparable injury. The obstetrician has long cried honestly against fœticide, that old commandment, Thou shalt not kill, and the gynecologist against Onanism, the limitation of families, and sterility. He considered the thought of breaking up this long-standing alliance between obstetrics and gynecology, which had taken the form of a resolution before the general session, sinful.

Dr. Joseph Taber Johnson, of Washington, D. C., then read a paper entitled

TETANUS FOLLOWING OVARIOTOMY.

So rare a complication of ovariotomy, and the recent interest in the transmissibility of tetanus, was his reason for bringing this case before the Section. The history of the case was, in brief, as follows: A solid growth, sarcoma of the ovary, the size of a child's head, was removed. The patient, who was aged sixty-one, recovered rapidly and without complication till, on the morning of the thirteenth day, she developed tetanus, and died on the third day of the disease and fifteenth day of the operation. She exhibited numerous muscular spasms, mind clear, jaws locked. The convulsions were especially active in the neck and back, and during their presence the pulse was notably weaker. The patient died of what appeared to be heart-failure. No other patient in his hospital was affected with this disease, and it was the only case which had occurred in it since the eighteen months it has been in operation. It seemed to him that there

was probably no outside influences. His horses were healthy and he does not drive them himself, so thought there could be no opportunity in this way. In all cases of inoculation the disease is contracted and the patient dies in a very few days, generally not more than three. His patient got along well till the thirteenth day. The author's case, the case of Homans, of Boston, and that of Richelot, of Paris, are the only cases of this complication he could find. The room in which the author had operated was thoroughly disinfected.

THE EQUINE ORIGIN OF TETANUS

has been thoroughly discussed by Verneuil, of Paris, and much interest brought out by his investigations. Tait thinks tetanus will continue to be a complication of ovariotomy, and one which we can hardly explain or eliminate. The practical point of the paper was to draw attention to the infective nature of this disease. He advised that care be taken as to infection, especially with horses.

This paper was discussed by Drs. Polk, of New York; Parvin and Price, of Philadelphia; and Gordon, of Portland, Me.

SECTION ON STATE MEDICINE.

FIRST DAY, TUESDAY, JUNE 25TH.

J. BERRIEN LINDSLEY, M.D., PRESIDENT.

DR. JOHN B. HAMILTON, of Washington, read a paper on

INTERNATIONAL COMITY IN STATE MEDICINE,

in which he referred to the international sanitary conferences which have been held in Vienna, Constantinople, and elsewhere. The practical results of these conferences have as yet been slight; but the mere fact of the calling of them together is an evidence that nations are waking up to a realization of the necessity of undertaking measures for mutual protection from disease. One of the absolute rights of states in the unwritten law of international relations is that of self-protection, and this includes the right of preservation from epidemics. The speaker referred with approval to the resolutions of the Montgomery Sanitary Conference Association, and asked that the Section adopt them as its own, and recommend them to the general body. These resolutions were to the effect that any nation having plague-centres within its limits should adopt measures to prevent their extension abroad.

On motion, the Section endorsed and adopted these resolutions.

DR. W. C. RIVES, of New York, followed with a paper on

THE IMPORTANCE AND ESSENTIAL NEEDS OF LOCAL BOARDS OF HEALTH.

The speaker said that it is to local and not to State boards that we must look for the most effective work. Boards of health should be established in all cities, towns, and incorporated villages, and they should have full powers to insure the carrying out of their recommendations. There were yet many obstacles in the way of a full realization of the wishes of sanitarians in this respect. There was a prejudice in the minds of many people against boards of health, and it should be the endeavor of all—physicians, clergymen, the press, and health boards themselves—to arouse a healthy public sentiment in favor of the establishment of local health boards.

DR. N. S. DAVIS, of Chicago, then read a paper entitled

THE AMERICAN MEDICAL ASSOCIATION AND ITS RELATIONS TO THE PUBLIC HEALTH,

in which he recounted the work of the Association in this respect in the past, and showed that sanitary matters were considered of paramount importance in the early history of the Association.

COLONEL GEORGE E. WARING, JR., of Newport, read, by invitation, a paper entitled

MODERN SANITARY CONDITIONS.

The speaker estimated that the institution of proper sanitary methods throughout the country would result in the saving of over three hundred and fifty thousand lives every year, taking no account whatever of the amount of misery and loss of productive labor, from preventable sickness, that would be done away with. A proper application of the arts of the sanitary engineer would suffice, therefore, to save to the country one thousand of its citizens every day, an estimate based upon no untried conditions, but resting upon the results already attained. He then referred to the relations of the biologist and sanitary engineer. Formerly the engineer's work was largely empirical, but now the biologist, in his researches into the cause of disease, had discovered the reason of the engineer's success. The two professions should work in harmony, and the labors of both were needed to effect the necessary reforms and to bring about the prevention of preventable diseases.

DR. BAKER said that there were some diseases whose spread was not prevented by the labors of the engineer, by drainage, and the removal of excrementitious matters. For the prevention of these diseases, of which small-pox and scarlet fever might be mentioned as types, there was need of isolation and disinfection, and these should not be overlooked by the sanitarian.

COLONEL WARING said that he had purposely confined his remarks to the work of the sanitary engineer and to the diseases preventable by his art, and had refrained from touching upon what was more strictly within the province of the physician.

DR. PERRY H. MILLARD, of St. Paul, Minn., then presented the

REPORT OF THE COMMITTEE ON UNIFORM MEDICAL LEGISLATION IN THE UNITED STATES,

and read a paper entitled

MEDICAL LEGISLATION IN THE UNITED STATES.

In this he reviewed briefly the progress of medical registration laws in the different States of the Union, stating that the best of these laws at present were to be found on the statute-books of Minnesota, Montana, Virginia, and North Carolina. Strange to say, or sad to say, opposition to effective laws regulating medical practice had come in no small part from the medical profession itself, and from the officers of teaching bodies. Now, however, in Minnesota at least, the profession was doing much to aid the proper execution of the law. As a direct result of the law now in force in that State, there was there a smaller proportion of physicians to the population than in any other State of the Union.

SECTION ON DISEASES OF CHILDREN.

FIRST DAY, TUESDAY, JUNE 25TH.

J. A. LARRABEE, M.D., CHAIRMAN.

THE CHAIRMAN called the Section to order, and read an

ADDRESS ON PÆDIATRICS,

which he said is not a forced specialty, as the diseases of children require particular study. He deplored the fact that so many practitioners are so unfamiliar with the symptomatology of infantile disorders. He considered that, from a proper deliberation on the subjects connected with diseases of children, wise and wholesome laws would originate to prevent disease. Infantile mortality, from preventable causes, is far greater than it should be. The Chairman expressed the hope that the Section would formulate and adopt some resolutions prohibiting the publication of any statements, either laudatory or condemnatory, of any proprietary preparations of infant foods.

Dr. T. B. Greenley, West Point, Ky., read a paper on

THE MANAGEMENT OF INFANTS DURING THE FIRST YEAR.

The paper dealt almost exclusively with gastro-intestinal disorders. The author spoke of the predisposing causes of mortality—intemperance, syphilis, etc. In feeding children he believed that pure cow's milk is better than the diluted milk. He objected to the use of starchy foods. If a wet-nurse be selected, she must be carefully watched, as she may neglect her foster-child, or administer an opiate or alcohol. Dr. Greenley considered that mothers who allow their infants to be nursed by hired women are often guilty, unintentionally, of infanticide.

Discussion was participated in by Drs. Sears, Whitney, Watson, Christopher, Brush, Latimer, and others.

Dr. E. F. Brush, of Mt. Vernon, N. Y., read a paper entitled

COW'S MILK FOR INFANT FOOD.

Dr. Brush commenced by saying that the medical profession was agreed that nothing equalled good cow's milk as a food for infants, and therefore it was to be regretted that attention had not been given by the profession to reforming the breed of cattle and the handling of milk, than to the question of substitutes for it. In milk for infant feeding there should be considered, 1, the variety of fats; 2, the amount of albuminoids; 3, the amount of salts; 4, the handling of the milk; and 5, the health of the cow. 1. As regards the fats, he pointed out that the usual processes of chemical analysis led to an underestimate of the fats in cow's milk, and that of these fats we have no late authoritative analysis, a neglect on the part of chemists which leaves us in doubt as to which of the fatty acids are the mischief makers in milk. These fatty acids have more to do with the development of poisons than have the albuminoids, and are the cause of digestive derangements. 2. The albuminoids vary considerably with the time or habit of extracting the milk, milk extracted every two hours not being likely to possess as much or as ripe albumen as that drawn off every twelve hours. In health the albuminoids are constant, but materially affected in disease. This change is not surprising when we examine the mammary sources of milk in disease, for then there are found inflammations, calculi, clots of fibrin, etc., while the gland is at the same time subject to infiltrations, tubercular deposits, and eruptive diseases. In all cases any variations in the amount of albuminoid must be ascribed to sickness. 3. The salts also have not lately been determined by chemists, and we do not know how constant the occurrence of these salts may be, though we can assert that they are influenced both by the health and the food of the animal. Hence the land on which a cow is pastured will indicate fairly what we may expect to find as salts.

THE NUTRITIVE VALUE OF THE SUGAR IS OVERESTIMATED,

as is shown by the milk of carnivorous animals. Condensed milk, or concentrated sugar of milk, is not to be recommended as an addition to milk, but cane-sugar should be preferred. The chemist's ideal food is a failure, and the idea that milk must contain such and such constituents in such and such proportions is a popular error. 4. The cow must be studied, "for milk is the scavenger of the cow's body," and if it does not nourish the infant she is sick, or the milk badly handled. A faulty condition of the cow is indicated by the albuminoids, bad food by the fats and salts, and bad handling by the ptomaïnes. The cow has an abnormally high temperature, her organs of generation are in unnatural activity, and she is made a machine for producing milk. It is no wonder then that she is, as a rule, an unhealthy animal. This delicate animal is rarely, owing to the low price of milk, fed properly, and the same cause compels the farmer to utilize every drop of milk, be the cow sick or well. Good food is the prime essential for producing good milk. 5. Milk is affected by its surrounding in the cow-house, and the method of

GETTING RID OF THE ODOR BY SALTPETRE

cannot be too severely censured, for the addition of the nitre united with the glycerides may produce poisons approximating to tyrotoxicon. No chemical substance should ever be added. Milk should not be conveyed a long distance, for travel deteriorates milk. Light, like heat, hastens decomposition, therefore glass bottles should not be used.

The milk ought not to be given to the infant warm, for then it coagulates like too old milk. Sterilized milk may be employed if we abandon all hope of improving the quality of milk.

To remedy these evils we should have a better cow, one not closely inbred, well fed with good sound food, and well attended to. The cheapness of milk is the reason why we have not better milk, and the inferior milk suggests the use of substitutes. If the price of the latter were added to the price of such milk, the extra money would enable the farmer to buy better cows and better food, and improve the quality of his products. This he ought to be compelled to do. Let us not recommend patent baby foods, but good, high-priced milk, and then if any trouble arises we can lay the blame on the milkman. Dairies for supply of infants' food should be under strict sanitary supervision. Such an ideal dairy should consist of spayed cows.

Dr. J. A. Jeffries, of Boston, spoke of the varying quantities of albuminoids and fats, as shown by Dr. Rotch's investigations. He thought milk-sugar preferable to cane-sugar in preparing milk for children. He would not advocate the sterilization of fresh milk, but would do it if the milk had to be kept.

Dr. Christopher, of Cincinnati, said that

MILK FROM SLOP-FED COWS

shows greater quantity of cream, but that it undergoes decomposition rapidly. He thought that the ptomaïnes are the cause of poisoning, and that the fats cannot produce them.

Discussion was also participated in by Drs. Early, Sears, Gates, Sheldon, and Latimer.

Dr. Brush, in closing the discussion, said that prepared foods of all kinds, even if only sterilized milk, always take a low place as nourishment compared with fresh milk. He stated that he can feed cows so as to increase the fat, but cannot increase the albuminoids. The albuminoids change very quickly when the cows are febrile.

Second Day, Wednesday, June 26th.

Dr. Max Einhorn, of New York, sent a paper which was read by its title,

THE TIME OF RETENTION OF FOOD IN THE INFANT'S STOMACH.

Dr. N. Guhman, of St. Louis; the paper was read by title,

SUMMER DIARRHŒA AND DYSENTERY.

Dr. Steele Bailey, of Stanford, Ky.; paper read by title,

CHOLERA INFANTUM: ITS ETIOLOGY AND TREATMENT.

Dr. Peter Hooper, of Philadelphia, read a paper entitled

INTESTINAL DISEASES OF CHILDREN DURING HOT WEATHER.

The author considered the causes of these diseases as mainly heat, impure air, and improper food. He believed the local abstraction of heat from the bodies of children suffering from entero-colitis or gastro-enteritis as productive of good. Cold water and ice internally, and cold compresses to the head he considered beneficial. He also believed in cooling the sick-room artificially by the use of large pieces of ice. The author gave the history of

a baby aged eight months, where a temperature of 109⅘° F. in the axilla was reduced in half an hour to 105° F. by the application of ice to the spine. The severe nervous symptoms were relieved by this treatment, though no med icine was given. Some entero-colitis followed the acute attack, but the child was always more comfortable when cold was used internally and externally.

In speaking of the use of milk-foods, the author related as his experience that the children who use them do not grow so strong, so muscular, or so rapidly as they should. In cases of failure of mothers to nurse their children he advised the use of sterilized milk.

The author mentioned as the possible treatment of the future in cholera infantum the opening of the abdomen and washing out of the intestinal tract. The use of inunctions of olive-oil were spoken of as beneficial.

Dr. S. Solis-Cohen, of Philadelphia, thought the use of ice preferable to antipyretics.

The Chairman thought that thermal diarrhœa is best treated by cold. He did not believe that cholera infantum ever began as a simple diarrhœa, as mentioned by the author. He spoke of the advantage of the use of small doses of morphine and atropine hypodermically, the effects being quick, and a dilatation of the peripheral capillaries thus relieving the intestines. He advocated the use of salines in entero-colitis in preference to castor-oil.

Dr. I. N. Love, of St. Louis, considered that the mother's milk is perfectly sterilized. He spoke of the physical inability of many mothers to nurse as being commoner than moral turpitude, although the latter is often given as a cause.

Dr. E. F. Brush, of Mount Vernon, N. Y., thought that the cases of acute gastro-enteritis in children were produced by the cows eating poisonous weeds.

Dr. W. P. Watson advocated the use of hot water as a drink for children with intestinal disturbances.

Discussion was also participated in by Drs. Whitney, Meyer, Jeffries, and Woods.

Dr. George Wheeler Jones, Danville, O.; a paper by title,

HEART FAILURE IN DIPHTHERIA.

Dr. T. E. Waxham, of Chicago, sent a paper on

INTUBATION OF THE LARYNX WITH REPORT OF CASES,

which was read by the Chairman.

During the past year the author operated 60 times with 28 recoveries, or 46.66 per cent., making the total number of operations 210 with 69 recoveries, or 32.85 per cent. He mentioned the increased percentage of recoveries. The author believed the increased success due to improved methods in feeding, greater experience, and better judgment in the management of the cases. He believed in the adoption of the inclined position with the head down in feeding or when drinking.

During the past year the youngest case operated on was six months old. Those that recovered under two years were aged fifteen months, and two aged eighteen months. Every case except one was characterized by membranous formation.

Dr. H. O. Bates, of Chicago; paper read by title,

INTUBATION OF THE LARYNX VS. TRACHEOTOMY.

Dr. G. W. Gay, of Boston, opened the discussion. He stated that of 327 tracheotomies at the Boston City Hospital, 95, or twenty-nine per cent., recovered; while of 223 intubations at the same institution, 47, or twenty-one per cent., recovered. He considered tracheotomy rather more successful than intubation. The new operation of intubation he thought more popular and easier to do. In 32 instances in which tracheotomy was done after intubation all but three cases died. Personally, he does intubations oftener than tracheotomy, because the tube requires less care. Was not positive about the effect of medicines in diphtheria.

The Chairman had done sixteen tracheotomies and saved four. Believed intubation a better operation in infants below one year of age, but thought that after that period tracheotomy, because of the increase in the strength of the trachea, was preferable.

Discussion was participated in by Drs. Dennison, Brush, and Whitney.

Dr. H. D. Chapin, of New York, read a paper on

PSEUDO-MEMBRANOUS RHINITIS.

The author asked the question if there can be a croupous inflammation of the nasal mucous membrane. Hartmann appears to be the first author to make the announcement that this disease is separate from diphtheria. The author reported two cases that he saw in consultation with Dr. Jonathan Wright. The patients were sisters, aged two and three years' respectively. The elder child was first attacked; she had been well until two weeks before the time when she was seen. She began with a discharge from the nose. Her general condition was good. An examination of the nose showed it to be packed with fibrinous material. The throat was only congested. There was almost no fever, although at one time the temperature reached 101⅘° F. The child played around. The baby exhibited about the same course of disease, except that the membrane was much more friable and not so abundant. Neither case presented any evidence of sepsis, and examination of the urine was negative. In view of the cases reported and of the literature of the subject, the author concluded that there is such a disease as pseudo-membranous rhinitis, but that it is extremely rare. He would make a diagnosis on constitutional conditions.

The paper was discussed by Drs. Whitney, Cochrane, S. Solis-Cohen, and the Chairman.

Dr. C. R. Early, Ridgeway, Pa., read a paper on

SCARLATINA.

Dr. Talbot Jones, St. Paul, Minn.; paper read by title,

PATHOLOGY AND TREATMENT OF CERTAIN COMPLICATIONS OF SCARLET FEVER.

ELECTION OF OFFICERS.

Dr. I. N. Love, St. Louis, was elected Chairman, and Dr. E. F. Brush, Mount Vernon, N. Y., Secretary.

SECTION ON DERMATOLOGY AND SYPHILOGRAPHY.

First Day, Tuesday, June 25th.

Dr. L. Duncan Bulkley, of New York, Chairman, called the Section to order, and proceeded to read his address, entitled

RECENT ADVANCES IN THE TREATMENT OF DISEASES OF THE SKIN.

Having no date, he said, from which to reckon the *recent* advance in the treatment of diseases of the skin, he looked over the field in a general way, considering the good and bad in treatment. He wished first to call attention to the fact that accuracy of diagnosis was essential to success in the treatment of diseases of the skin; intelligence in the application of remedies could alone secure results which were not disappointing.

It should be borne in mind that the same measures would act differently in different stages of the same disease. In giving results of new remedies one should state the stage at which it had been employed. Antagonistic elements should be removed.

The first advances to be noted were in

MECHANICAL THERAPY.

They were of various forms. The curette was useful in lupus, in the removal of moles, warts, etc. The cutaneous punch was also of use in removal of warts, moles, and acne. Multiple scarification with the scalpel or knife served an excellent purpose in certain cases of lupus, and gave good results in some nævi and rosaceæ.

ELECTROLYSIS

had come to play an important part in the treatment of skin affections, as in destruction of superfluous hair, nævi, and producing absorption of tumors.

The galvanic current was of value in the removal of pain, of herpes zoster, in pruritus, eczema, and conditions calling for the actual cautery. He regarded faradism of doubtful value in acute rosaceæ. Ichthyol and resorcin had not been as fruitful of good results as he had expected on reading Nunna's original contribution on their use. Speaking of strength of these remedies, he said two per cent. of ichthyol was strong enough to begin with, three to ten per cent. of resorcin. They were of use in acute eczema.

Nunna had devoted some time to the development of ointments in plasters, for the purpose of longer retaining the medicament in a given locality. They had not yet been much employed in this country. They were apt to prove too drawing. Plasters with rubber, mostly made in this country, were apt to prove too hot and drawing. Another agent for carrying remedies was made of glycerine and jelly, useful in dry, scaly eczema. Considerable had been expected of lanolin, but its field of application was very limited. Combined with other fatty ingredients in about twenty-five per cent., it often aided in keeping the skin soft. Its use in causing more rapid absorption by the skin was limited. The service rendered by petroleum preparations was undoubtedly great, but he spoke a word of caution against their too common use in ointments. Care was also needed in the use of salicylic acid. It was an efficient parasiticide. Chrysarobin was well known to have the power of dispelling the lesions of psoriasis. Antharobin was nearly as efficient, and did not have its staining effect. The value of naphthol in scabies and menthol in pruritus were mentioned. A combination of camphor and carbolic acid had recently proven valuable in relieving itching of the skin.

Although attention had been principally directed to local measures, yet diet and internal remedies should always be borne in mind when making use of these.

THE TREATMENT OF TINEA TONSURANS.

Dr. W. T. Corlett opened the brief discussion which took place on this subject. He had treated a few cases with bichloride of mercury and applications of galvanism, but there had been no evidence to show that the latter agent had been of any service.

Dr. Garlock did not employ epilation in treatment.

Dr. Frederick J. Leviseur, of New York, thought parasiticides in tinea tonsurans acted by killing the fungi with which they came in immediate contact; that they could be made to penetrate the superficial layers of skin, and meet and destroy the fungus in the cells; and, by irritating the deeper layers, would in the course of time completely eliminate the parasite, and effect a cure. He continued the discussion with a paper,

PROPHYLAXIS OF RINGWORM OF THE SCALP.

European governments took precautions to prevent the spread of this contagious disease, and he had been surprised to witness the apathy shown regarding it in this country. It was to be seen in children going to public schools, and in those in other institutions, and epidemics were not unusual. Failure to diagnosticate it was common. The fungus should be sought for under the microscope, in all doubtful cases. Its presence was conclusive, but failure to find it was of negative value. Some domestic animals were capable of transmitting ringworm to man. He thought there should be in all centres a place for the isolation and free treatment of these cases. The public would thus learn of the contagiousness of the affection, its nature could be better studied by experts.

Dr. Shoemaker had treated some cases in an epidemic by extracting the hair, others without it, and the latter seemed to recover more quickly. He was in accord with the author, however, with regard to the importance of prophylaxis. Oleate of mercury and oleate of copper had shown their power in destroying the parasites. Many of the patients who were anæmic responded better to treatment under improved hygiene and diet.

Dr. Bulkley had known the affection to spread very rapidly in institutions. In some cases it was extremely rebellious to treatment. He had been treating one case during months without apparent benefit. The child was robust. In half the cases the disease was a trivial affair, responding readily to treatment.

Dr. Wykoff, speaking of treatment, had cured a case by chrysarobin after other measures had failed.

Dr. D. W. Prentiss, of Washington, read a paper, entitled,

CHANGE IN THE COLOR OF THE HAIR FROM THE INTERNAL USE OF PILOCARPINE.

He first referred to two cases of his own already published, the first in the *Philadelphia Medical Times*, July 2, 1881, in a lady aged twenty-five, who employed pilocarpine to relieve uræmic symptoms resulting from anuria. Her hair changed from light brown to black. The other he published in the *Therapeutic Gazette*, April 15, 1889, that of a lady aged seventy-two, who took jaborandi for disease of the kidneys, whose eyebrows changed from white to black.

The author then quoted cases from German and other medical literature, in which the use of pilocarpine had caused the hair to grow where it had fallen out, in some instances the new hair having a different color from the old.

It had been doubted by many eminent in the profession whether the hair ever changed color suddenly. To settle that question, he had searched the library of the Surgeon-General's office, and found records of indisputable cases. In some the change in color had been sudden, in some not so rapid; in some it was due to fright or other mental influence. He went on to show the change in color of the hair, feathers, or bones of different animals, according to the food which they received, or change of seasons.

His conclusions were: 1. In the human subject the only agent, as far as he was aware, which had been charged with changing the color of the hair when administered internally was jaborandi. 2. Cayenne pepper, in changing the color of canary birds to orange. 3. The change in color of parrots by the Indians of the Amazon, from green to yellow and red; by feeding with the fat of a certain kind of fish. 4. The restoration of certain birds to their original brilliant colors at the zoological garden, Amsterdam, by feeding a kind of shrimp or small crustacean. 5. The effect of madder in staining the bones of pigs red, and of poke-berries coloring crows' bones purple. It might be of interest to study the influence of diet and habit upon the color of hair in different nations of men.

Dr. Bulkley had found pilocarpine cause the growth of hair in alopecia areata in a few cases, while it failed in others.

Dr. J. V. Shoemaker, of Philadelphia, read an abstract of a paper, entitled

SOME NOTES ON HOANG-NAN.

The drug was allied to nux vomica, and produced similar symptoms when administered to animals. It stimulated the functions of the skin, and while he had found it of some benefit in affections with this indication, yet in general it had not fulfilled the expectations excited by some enthusiasts. It had a high reputation in leprosy. He had had opportunity to use it in but one case. Its effects on the disease were negative. It could be obtained in fluid extract or tincture. Of the former preparation he gave not more than thirty drops, before meals.

SECOND DAY, WEDNESDAY, JUNE 26TH.

ELECTION OF OFFICERS.

DR. I. E. ATKINSON, of Baltimore, was elected Chairman, and Dr. W. T. Corlett, of Cleveland, was re-elected Secretary.

THE ETIOLOGY OF LEPROSY, A CRITICISM OF SOME PRESENT VIEWS.

DR. P. S. ABRAHAMS, of London, sent the paper, which was read by the Secretary. The supposed etiological factors of late years were three: heredity, diet of fish, contagion. The two first named were rejected by the author, who quoted the views of American authors. together with the statistics of leprosy in this country. Hutchinson almost alone held that the disease was caused by the consumption of fish, especially that which was partially decomposed. The author held the view now commonly entertained, that leprosy was contagious, although only mildly so.

The Chairman, Drs. Garlock, Fordyce, and others who made some remarks, could give no evidence from personal observation of contagion, although they believed the disease to be transmitted in that manner.

DR. CORLETT said there were some lepers in the Paris and London hospitals all the time; they were not isolated; the disease was regarded as contagious only in the way that syphilis was contagious.

DR. L. D. BULKLEY opened a discussion on

THE INDICATIONS FOR, AND DURATION OF, THE TREATMENT OF SYPHILIS,

by propounding certain questions: 1. How early should treatment of syphilis begin? 2. Should one wait until positive diagnosis could be made? 3. How long should the treatment continue? 4. How soon could the patient be allowed with safety to marry? 5. When the disease had become thoroughly established, should treatment be continued longer than the presence of symptoms? If so, how much longer?

The discussion was continued in a paper sent by DR. EPHRAIM CUTTER, of New York,

THE POSITIVE DIAGNOSIS OF SYPHILIS,

read by his son, who said he could confirm all that was stated in the paper. The diagnosis was based on the examination of the blood under a good microscope for the crypta syphilitica, oval spores of a copper color, which had peculiar movements in the blood. One of experience could not mistake the spore for any other which might happen to be in the blood. Its presence afforded unmistakable evidence of syphilis.

DR. SEILER, of Philadelphia, said that just ten years ago he put the same question to Dr. Ephraim Cutter which he did to-day to his son, and received the same answer, that he could not state the measurements of the spore in question. Dr. Seiler thought it was simply broken up blood-corpuscles.

DR. BRUSH, of Philadelphia, had been unable to verify the observations of Dr. Cutter, as had Dr. Matthewson, of New Jersey, and others who spoke.

DR. SEILER said with regard to the treatment of syphilitic gummata, that he thought it should be continued long after disappearance of the lesions, say two years.

DR. CORLETT preferred to await active treatment until positive diagnosis of syphilis could be made. In a few cases in which he had destroyed the syphilitic chancre, the subsequent course of the disease seemed to have been less severe than usual. Mercury was the only drug with which he had been enabled to obtain permanent relief from syphilitic manifestations.

DR. GARLOCK had found mercurial inunctions sometimes prevent the appearance of secondary symptoms.

DR. FLEISCHNER, of New Haven, observed that some cases of syphilis were known to run a mild course. That being true, he doubted whether a uniform rule should be made of treating all cases in the same heroic way, continued always two or more years after cessation of symptoms. Treat each case individually.

THE CHAIRMAN thought it not safe to leave off treatment until two or three years. He sometimes consented to marriage within a year after contraction of syphilis, if during the last six or eight months there had been absence of symptoms, and, in such cases, the disease had not been given to the wife or offspring.

DR. CARL SEILER, of Philadelphia, then read a paper entitled

THE RELATIONS BETWEEN ACNE AND DISEASES OF THE NASAL CAVITY.

The past ten years he had observed a great many cases of acne in connection with diseases of the nose, the acne coming and going with the appearance and disappearance of nasal irritation. Acne punctata was observed to be almost invariably associated with atrophic rhinitis, while acne rosacea was associated with hypertrophic inflammation of the nose. It was known that the blood-supply of the turbinated tissue was intimately connected, through the nerve-supply, with that of the skin of the face. The author believed the function of the erectile tissue of the turbinated bones and elsewhere to be that of taking up the overflow of blood of neighboring parts observed in mechanical or nervous irritation. Relief of the nasal difficulty, in many of the cases which had come under his care, caused the acne to disappear without other treatment, local or internal. The connection between the skin affection and that of the mucous membrane of the cavity, seemed to be both mechanical and nervous, or reflex, the one reacting upon the other.

DR. E. N. BRUSH, of Philadelphia, read a paper on

DERMATITIS EXFOLIATIVA,

in which he narrated two cases of desquamation of the skin in insane patients in the institutions of New York, the falling off of the epidermis being preceded by very general pigmentation of the skin. The cases suggested a possible relation between the skin disease and that of the nervous system.

DR. GARLOCK related a case of

EXFOLIATIVE DERMATITIS

in a man, which he attributed to a depreciated vital state, caused by overwork and bad sanitary surroundings.

DR. FLEISCHNER reported a case of

PTYRIASIS RUBRA,

caused by rapid changes from a hot, dry air, to the cold air of a refrigerator; Dr. Flandrau, the case of a lady, who a number of times had a reddening or inflammation of the entire body, followed by falling off of the cuticle in fine particles, possibly due to the influence of financial losses.

THE CHAIRMAN mentioned two cases in girls in the Skin Hospital, one of whom died after a stay in the hospital of four years. In this case a thorough post-mortem examination was being made. The other patient had been in the hospital six years. Her entire body was as red as a boiled lobster. Nothing had proven of benefit. She kept the surface covered constantly with vaseline.

SECTION ON LARYNGOLOGY AND OTOLOGY.

FIRST DAY, TUESDAY, JUNE 25TH.

W. H. DALY, M.D., CHAIRMAN.

THE CHAIRMAN read a short address on

MARKING AN EPOCH IN LARYNGOLOGY.

He referred to his formerly expressed remarks in regard to the necessity of the otologist possessing skill in dealing with diseases of the larynx and naso-pharynx, and especially the surgical treatment of the latter, thus associating the specialty of otology with that of laryngology, rather than with that of ophthalmology, with which it has

been usually associated in the past. This placing otology in its proper relations is what constitutes the epoch in these specialties.

Dr. John McKenzie, of Baltimore, reported a case of

LYMPHOID TUMOR, ORIGINATING IN THE FLOOR OF THE RIGHT PYRIFORM SINUS,

and threatening suffocation when the patient was in a recumbent posture.

The patient, a clergyman, aged forty-two, had never had any throat trouble, and was otherwise perfectly healthy. There was no assignable cause for the growth, which, on microscopical examination, was found to consist entirely of the lymphoid tissue of the pharynx, recently described by Waldeyer and his pupils.

The tumor was removed by first exciting gagging, so as to throw it as far as possible up toward the back of the tongue. It was then caught with a pair of laryngeal forceps, and with these as a guide the écraseur was passed over the tumor and it was rapidly cut through.

Dr. McKenzie remarked that growths of various kinds are occasionally found on the pillars of the fauces, glosso-epiglottic fossa, and upper pharynx; but tumors originating in the pyriform sinus are exceedingly rare, and that the growth described is unique.

Dr. Solis-Cohen said that it was rather curious that this unique growth originated in the position in which so few cases of lipoma had their origin.

Dr. W. Freudenthal, of New York, read a paper on

THE CONNECTION BETWEEN CHRONIC DISEASE OF THE UPPER AIR-PASSAGES AND HERNIA.

In continuation of his observations, formerly published, the author found that in accordance with the frequency of nasal disease herniæ are found in the following proportions: In the United States, in 50 out of 1,000 conscripts; in France, in 22.87 out of 1,000 conscripts; in Italy, in 16.61 out of 1,000 conscripts; in Austro-Hungary, in 14.09 out of 1,000 conscripts; and in Germany in less than 14 out of 1,000 conscripts.

Furthermore, the author proved the correctness of his theory against Dr. Schpinger, who had affirmed the contrary opinion.

In women hernia are rarer than in men, on account of the weaker stress used in the act of coughing, clearing the throat, and the like.

Dr. J. H. Bryan, of Washington, D. C., read a paper on the

DIAGNOSIS AND TREATMENT OF DISEASES OF THE ANTRUM.

The author remarked that of the surgical affections suppurative inflammation plays the most important part; until recently it was regarded as a rare condition. It occurs generally after the first dentition. Among its causes are: 1, traumatism; 2, acute infectious diseases, 3; syphilis; and 4, extension of inflammation from carious teeth. The condition called hydrops antri generally results from catarrhal affections of the nose, in which the secretion is seromucous; but where it is muco-purulent it results from extension from diseased teeth.

There are four conditions, after eliminating wounds and exanthemata, that may give rise to pus in the nasal chambers: 1, foreign bodies; 2, disease of bone; 3, secretion of pus from the antrum of Highmore; and 4, secretion of pus from the frontal sinus and anterior ethmoid cells.

The indication for treatment of abscess of the antrum is to let out the pus, drain, and disinfect; if the abscess point anywhere, it should be opened there. The tendency of practice is to open these abscesses through the nose, returning to the method of Hunter, after a century, during which the practice has been to open through the mouth.

The operation most approved is Cooper's—that through the alveolar process. It has these advantages: 1, It affords the best means for draining and disinfecting; and 2, it can be performed without anæsthetics. On the other hand, it offers facilities for the entrance of food and bacteria, and it sometimes necessitates the extraction of a sound tooth. Mikulicz opens through the lateral wall of the nose where it is thin. This operation gives easy drainage and washing of the cavity, and there is little danger of entrance of foreign particles.

Local treatment is very important, including irrigation by mildly disinfectant fluids. Permanganate of potash best overcomes fetor. A syringe specially adapted to washing out the antrum from this point was shown by the author, and several cases were reported in illustration of the subject.

Dr. J. B. Lippincott, of Pittsburg, said that he was under the impression that purulent disease of the antrum was frequently due to morbid conditions of the teeth. Abscess of the orbit frequently arises from the antrum, which has itself its primary cause in carious teeth.

Dr. E. Fletcher Ingalls, of Chicago, had treated several cases of the kind. One had been cured after about three weeks' treatment, having been washed out repeatedly with peroxide of hydrogen, through the normal opening into the nasal cavity. However, he had three cases under observation where every form of treatment had been inefficient in checking the purulent discharge. They had worn tubes in the alveolar process for periods of five, three, and two years respectively, and in none of them did there appear to be any dead bone, as the discharge was not offensive.

The Chairman remarked that he had had considerable experience in opening abscesses of the antrum, and that the operation was not without grave danger at times, and in proof referred to a well-known medical man who lost his life by it.

(To be continued.)

Stable Bichloride Solutions.—Dr. Robert T. Morris, of this city, writes: "Bichloride of mercury solution is frequently made in a wash-bowl; and blood squeezed from sponges into this solution renders the bichloride inert in a few moments. It is a well-known fact that several of the acids in solution with bichloride of mercury will prevent this destruction of the salt in the presence of albuminous fluids, and at my suggestion Mr. Painter, of the Brunswick Pharmacy, keeps in stock tablets composed of bichloride of mercury, tartaric acid, and chloride of ammonium. One of these tablets dissolves in a pint of water in about ninety seconds, making a 1–2000 solution of the bichloride that is stable in the presence of albumen.

Prolonged Gestation.—Dr. E. J. Abbott, of St. Paul, Minn., writes: "*À propos* of a case of prolonged gestation noted in your issue of May 18th, I wish to report a still more prolonged case. The last menstrual period was from April 3 to 6, 1888. Symptoms indicating a possible pregnancy began to manifest themselves about May 1st. Quickening was thought to be felt the latter part of September, and was pronounced early in October. Delivery took place April 20, 1889, more than a year after the cessation of the menses, and more than six months after quickening had become unmistakable. The child was delivered with forceps and weighed ten and one-half pounds."

An Antiseptic Pocket-Case.—Dr. George F. Leick, of Cleveland, writes: "In your issue of May 18th, Dr. Bradshaw, of Orange, N. J., makes a plea for a pocket-case meeting the rules and requirements of modern surgery. Such a case is made by Chr. Schmidt, of Berlin. Being entirely of metal (German silver) all the instruments being nickel-plated, bistouries in one piece, silk contained in the handle of the needle-holder it is what Dr. Bradshaw asks for. The case is known as Bergmann's. I have carried one during the past year and am entirely satisfied with it."

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, June 29, 1889.

THE FORTIETH ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

THE meeting of the American Medical Association, held this week in Newport, a full report of which, prepared by our special correspondents, we present in this issue of THE MEDICAL RECORD, was in some respects a notable success. The attendance, especially of Western members, as compared with that of some of the previous meetings, was small; but what the meeting lacked in numbers was made up by enthusiasm, for notwithstanding the attractions in the way of afternoon excursions offered by the profes sion of Newport, the meetings of the several Sections were well attended. Some of the papers presented, notably in the Surgical and Laryngological Sections, were of unusual interest, and constitute valuable contributions to medical literature. The lack of hotel accommodations caused considerable individual discomfort, and has demonstrated the unwisdom of selecting any but the larger cities for the places of meeting of the Association. In view of this fact we cannot but regret that the Association has decided to assemble next year in Nashville, in preference to either Philadelphia or Detroit, which cities were under consideration, but were passed over by the committee. Nashville is a beautiful city, and the hospitality of its citizens is famed; but, we fear, as has happened at Newport, that it will be impossible to provide comfortably for all the visitors. The subject of higher medical education received its share of attention, but seemingly failed to arouse that degree of enthusiastic approval which its importance demanded. The annual plea in behalf of the Rush monument was made, with somewhat more than the ordinary force, Dr. Pepper aiding it in his address; but the response in the way of contributions to the fund was not as encouraging as it might have been. We would remind the committee, however, that this is the common experience of monument committees, and if they will only have patience and perseverance they or their successors may live to see the fruition of their hopes.

The profession of Newport should receive the thanks of the Association for the most creditable manner in which the duties of a host were performed. The entertainments were varied, but unfortunately the most attractive of them were offered in the afternoon, at which time the members were busy in Section work. It is to be regretted that the Western representation was not larger; but in spite of this drawback the meeting was one of unusual interest, and must be classed among the most successful ever held by the Association. The choice of President for the coming year was a most happy one, and we extend our congratulations to both the Association and its new President upon the honor which has come to both in this fortunate selection.

THE NOTIFICATION OF INFECTIOUS DISEASES AND IMPRISONMENT OF PHYSICIANS.

SYSTEMATIC writers agree that while there is no one symptom pathognomonic of yellow fever, yet its diagnosis is almost always possible. Such diagnosis is made easier since the blood-test for the malarial plasmodium makes the exclusion of malarial fever so much more certain. In view of these facts and of the slight contagious properties of yellow fever, the Brooklyn Board of Health is entitled to the severest criticisms for its stupid and blundering conduct in imprisoning a physician because he failed to report a case of malaria which the Board considered one of yellow fever. The facts, we believe, are that Dr. Duncan, of the steamship Colon, was attacked by a remittent fever, and was attended by Dr. Bogert. The Brooklyn Board of Health got knowledge of the case, removed the sick man to Swinburne's Island, quarantined the patient's house, and imprisoned Dr. Bogert in it. Dr. Duncan, despite the peril of removal during the height of his illness, has fortunately recovered, and Dr. Bogert, after being arrested, imprisoned, and threatened with a suit, was finally set free, though not until he had suffered much inconvenience.

Another patient on the same steamer, who was supposed at first to have yellow fever, was removed, while still sick, from her hotel, and subsequently died.

These cases, which suggest one not unlike them that occurred in this city some months ago, if they continue, will soon become a reproach and scandal to preventive medicine. It ought to be possible to keep out dangerous diseases without slaughtering innocent victims of malarial fever, and without working public feeling into a hysterical state over every sporadic case of an infectious character. New York is in no danger of a yellow-fever epidemic. With our present sanitary arrangements such a thing is almost an impossibility; and it is nothing less than brutal to rush suspected cases, while at the height of the disease, to some remote quarantine station.

Apart from this comes another question, of immediate personal interest to the profession. Must a physician be subjected to arrest for not reporting cases of remittent fever to the local authorities? If so, we have reached a curious stage in State medicine. It should be borne in mind that the State has no constitutional right to lay the responsibility of notification upon the doctor. He is not a public servant; and he has received no special privileges from the State. The laws that exact from him the duty of notification of infectious diseases are purely arbitrary, and have not been contested by physicians because of the public spirit of the medical profession. If these laws are, however, to be so interpreted as to be a continuous source of annoyance and danger to personal liberty, they will cease to be enforced. We trust that the Brooklyn Board of Health will make proper amends to Dr. Bogert, and learn some lessons in diagnosis and discretion from his case.

TOBACCO-CHEWING AS A PREVENTIVE OF PHTHISIS.

Texas is not only a great State topographically and superficially, but it is the source of ideas whose freshness and originality continually surprise and instruct one. The hygienists of Europe have been for some time past laboriously studying the best methods of preventing phthisis, with the result of reducing everything to a laborious, uncertain, and disagreeable battle with an expectoration. A Texas physician, Dr. J. Walter Cock, of Waco, by a flash of genius renders unnecessary the scrubbings, disinfectants, and spit-cups of science, and shows that phthisis may be kept off by the simple process of chewing tobacco. He says (Texas *Courier-Record*): "From observation and inquiry extending over the past twenty-five years, I can announce that chewing tobacco from about the ages of twenty to thirty, by those predisposed to tuberculosis of the lungs, will prevent its development. I suppose this opinion, or rather conviction, has in my experience been verified in some hundreds of instances."

He adds: "My present views are that tobacco chewing acts as a protective agent by counteracting the plethoric conditions of adolescence, and that it acts also locally as a curative agent in destroying the tubercle bacillus."

Dr. Cock specifically insists that it is chewing, not smoking, which keeps off phthisis. The arguments for his views are not perhaps entirely conclusive, although we are informed that more will be contributed to the subject later. They represent the large experience of a gentleman who lives in a region where the prophylactic value of tobacco juice can, it is said, be abundantly tested.

We take it for granted that the ladies of Texas do not chew tobacco, and we are surprised that Dr. Cock does not bring into his argument the fact that, in Texas, the mortality from phthisis is considerably less among men than women, being in 1880, 615 males to 752 females, while in a northern State, like New Jersey, where tobacco-chewing has largely given way to more insidious vices, the male mortality is the greater.

Dr. Cock's arguments, when they have been a little further fortified, will bring dismay into the camp of the anti-tobacconists, and perhaps will cause a slight flutter in the gentler sex, who must be not only denied the juicy privilege of saving their lives by masticating narcotics, but must endure the somewhat unpleasant spectacle of seeing their husbands, brothers, and sweethearts discolor their mucous membranes in order to avoid tuberculosis.

MISSOURI PHYSICIANS AND THE STATE BOARD OF HEALTH.

The Missouri State Board of Health has been obliged to adjourn *sine die*, because the Legislature refused to appropriate any money for its expenses.

This action of the Legislature is not so much a reproach to the lawmakers as it is to the physicians of the State of Missouri. They must be cast in a poor mould, indeed, if they have not sufficient character and influence to impress upon the public the importance of State medicine and sanitary work. We read in the Kansas City *Medical Record* that the Missouri State Medical Association met at Springfield on May 22d, and that the subject of the State Board of Health was presented to the Society, but too late for action. It appears, also, from the comments of our contemporary, that Missouri physicians have been too anxious to get a State Board whose chief purpose should be to drive out quacks. Naturally, to the average legislator the medical support of this particular branch of sanitary science is not entirely disinterested. In the organization of a Health Board it can be but one factor, and apparently in Missouri it must be a minor one.

HYDROPHOBIA.

It is getting somewhat trying to the patience to read the vapid and foolish reiterations of certain estimable gentlemen who don't believe in Pasteur, or hydrophobia, or preventive inoculations. The ebullitions of weak judgment and inconsequent logic can be tolerated occasionally, but they should not be allowed to overburden current medical literature. There is nothing better established in science than the existence of rabies, both in man and the lower animals. The investigations of careful and conservative experts, such as Mr. Victor Horsley, support the views and endorse the work of M. Pasteur. Those that deny its value should first show themselves capable of judging experimental work, and cease to juggle with figures, or work themselves into rhetorical fury over questions which they so conspicuously misunderstand.

News of the Week.

Professor Kahler has been installed as Professor of the Practice of Medicine in the University of Munich, succeeding the late Professor Bamberger.

The Woman's Medical College of Baltimore has adopted a three years' compulsory course.

There has been an Epidemic of Trichinosis at Lille, France, from eating pork.

The Rights of the Reviewer.—Medical reviewers will breathe a little easier on learning that in the suit for libel, brought by Dr. Tibbetts against *Nature*, the jury brought in a verdict of one farthing damages. The suit was on account of a very severe criticism on Dr. Tibbetts' book, which appeared in *Nature*.

The Pancreas and Diabetes.—Drs. J. Von Mering and O. Minowski have found that the extirpation of the pancreas in dogs uniformly causes a persistent diabetes.

The Baltimore Physicians have contributed $186 to their suffering professional brethren of Johnstown.

The New York Hospital Library.—At the last meeting of the board of governors of the Hospital a fine portrait of the esteemed librarian, Dr. John L. Vandervoort, was presented to the board by Dr. George L. Peabody, who originated the movement among the friends of the institution to procure the portrait.

Dr. Theodore P. Mayo, well known as surgeon in the Army of Northern Virginia during the war, died at Richmond, Va., on June 21st, aged fifty-nine.

Inoculation of Cancer.—It is stated in *La Semaine Médicale* that Hanau, of Zurich, has succeeded in transferring the carcinoma of a rat to two animals of the same species.

The French Association for the Advancement of Science meets at Paris, August 8th to 14th. The Medical Section is presided over by M. Trelat.

MEDICAL LIBRARY OF THE BOSTON CITY HOSPITAL.

INDEX.

A dictionary superstition, 18.
Abbe, Dr. Robert, a contribution to the surgery of the spine, 149.
Abdomen, gunshot wounds of, 604.
Abdominal and pelvic surgery, statistics of, 354.
Abernethy, John, 252.
Abortion, criminal, by blowing air into the uterus, 214; in the Sandwich Islands, 474; prevention of, in Vienna, 670.
Abortionists, an attack on, 47.
Abscess, pelvic, pyelitis resulting from, through compression of the ureter, 285; psoas, trephining the pelvis for, 383; pulmonary, following the retention of a nail in the bronchus for a year, 290; pulmonary, simple, non-tubercular, non-metastatic, 469; traumatic, of the brain, 320.
Abscesses, pelvic, complications in opening, 245; suppurative, of the uterine appendages, treatment of, 245.
Achorn, Dr. J. Warren, a unique examination for hospital appointment, 556.
Acetonuria, relation of, to diabetic coma, 127.
Acid, camphoric, 308; salicylic, differences in, 243.
Acne, treatment of, without arsenic, sulphur, ointments, or lotions, 497.
Acoustics of the human chest, application of, in physical diagnosis, 158.
Acromegalous giant, 244.
Actinomycosis hominis, 276, 302.
Acupuncture in enlargement of the spleen, 559.
Addison's disease, 190; pathogeny of, 295.
Adenitis, acute multiple, and œdema of the larynx, 663.
Adenoid hypertrophy at the vault of the pharynx, 664.
Adeno-sarcoma of the uterus with pyometra, 346.
Adulteration of food, bill to prevent, defeated, 383; in Paris, 473.
Agaricine in sweating, 638.
Agnew, Dr. C. R., a reminiscence of, 140.
Agnew memorial fund, the proposed, 492.
Air-passages, disinfection of, with myrthol, 379; upper, frequency of disease in the, 328; manifestations of lithæmia in, 668; œdematous form of disease of the, 663; relations of chronic disease of, and neurasthenia, 664; syphilis of, 665.
Alabama, experiences of medical examining boards in, 381; State Medical Association, home for, 496.
Albinismus, 292.
Albuminuria, febrile, in childhood, 491.
Alcohol in bond, use of, by scientific institutions, 467; in medicine, 70.
Alcoholics, beer compared with other, 671.
Alcoholism, and heredity, 571; chronic, morbid anatomy and pathology of, 27, 82, 193.
Alkaloids of cod-liver oil, 160.
Allen, Dr. Nathan, notice of book by, 577.
Allingham, Mr. William, notice of book by, 185.
Alopecia areata, a clinical study in, and its treatment, 231.
Alpine winter in its medical aspects, book notice, 468.
Amenorrhœa, medicinal treatment of, 129.
American Laryngological Association, 662.
American Medical Association, fortieth annual meeting, 701; editorial on, 728; Section on Dermatology and Syphilography, 724; Section on Diseases of Children, 722; Section on Laryngology and Otology, 726; Section on Obstetrics and Diseases of Women, 719; Section of Practice of Medicine, Materia Medica, and Physiology, 711; Section on State Medicine, 722; Section on Surgery and Anatomy, 714.
American physicians, protection for, 55.
American posture, the, 601.
American Surgical Association, annual meeting, 579, 604.
Amidon, Dr. R. W., on the uses of electricity in medicine, 362.
Amnion, functions of the, 320.
Amputation of the thigh of a three days' old girl, 461.
Amyloid degeneration, recent studies in, 211.
An illustrated encyclopædic medical dictionary, book notice, 101.
Anæmia and chlorosis, differential diagnosis, 12.
Anæsthesia, new use for ether during, 14.
Anæsthetic inhaler, a new, 642.
Anæsthetics, and effeminacy, 44; quality of, in New York, 19.
Anatomical and physiological memoranda, 321.
Aneurism, aortic, cure of, by ligating the right common carotid and subclavian arteries, 327; aortic, iodide of potassium in, 345; interesting case of, 553; new treatment of, 356; of the abdominal aorta, 25; of the arch of the aorta; sudden death without rupture, 88, 108; of the subclavian, cure of, 298; traumatic, in a child under one year, 93.
Aneurisms, cerebral and aortic, causes of rupture of, during sleep, 287.
Anchylosis of the knee-joint as a remedy for the "dangle-leg" due to infantile paralysis affecting the entire limb, 367.
Angioma, electrolysis in, 181.
Animals, disease communicated to, from man, 278.
Anodal diffusion, 471.
Antifebrin, local application, 440.
Antipyretics, action of, on tissue metabolism, 215.
Antipyrin and sweet spirits of nitre, incompatibility of, 244; in chordee, 308; in chorea, 356; in laryngismus stridulus, 345; in locomotor ataxia, 570; in rheumatism, 70; in typhoid fever, 66; in rashes, 289; substitute for, 323; tippling, 691.
Antirrhinum majus, glucoside of, 167.
Antisepsis in new-born children, 69.
Antiseptic surgery at the Hospital de la Salpêtrière, 168.
Antiseptics in normal labor, 610; in the treatment of summer diarrhœa in children, 237.
Anuria, 445.
Anus, fissure of, spasmodic urethral stricture from, 85, 105; stretching the sphincter of, for obstinate constipation, 261, 273; treatment of fistula of the, 169.
Aorta, abdominal, aneurism of the, 25; aneurism of, causes of rupture during sleep, 287; aneurism of, cure of, by ligating the right common carotid and subclavian arteries, 327; aneurism of, iodide of potassium in, 345; aneurism of, sudden death without rupture, 88, 108; rupture of the, 25; tubercle in the, 380.
Aortic insufficiency, slight, 671.
Apex-beat, situation of, in children, 14.
Apomorphine, dangers of, 250.
Appendix vermiformis, inflammation and gangrene of, 694; laparotomy for perforation of, 449.
Appetite, boyish, 531.
Aqua menthæ, what is? 83.
Armstrong, Dr. A. A., injurious effects of cocaine, 475.
Army News, 28, 56, 84, 111, 167, 194, 224, 251, 280, 307, 336, 364, 390, 420, 448, 476, 503, 530, 558, 615, 642, 670, 699.
Army, report of the Surgeon-General of the, 242.
Arsenic, diffuse pigmentation produced by the internal use of, 472, 700; in the home, 132.
Arsenical poisoning, chronic, 657; from green candles, 354.
Arteries, torsion of, for the arrest of hemorrhage, 606.
Arthritis, universal suppurative, 106.
Artificial feeding in children, 234.
Ascent of man, 440.
Ascites simulating ovarian tumor, 392.
Aspirator needle plunged through the pleural cavity and diaphragm and into the liver, with fatal effect, 267.
Association of Acting Assistant Surgeons, United States Army, 221.
Association of American Physicians, preliminary programme of the, 635.

Clark, Dr. Alonzo, and microscopy, 305.
Clark University, 660.
Cleveland, Dr. Clement, stretching the sphincter ani as a method of cure in obstinate constipation, 261.
Clinical uses of rare diseases, 669.
Clothing and colds, 391.
Club-foot, apparatus for, 450.
Cocaine, artificial, 184; in hay-fever, warning against the use of, 392; injurious effects of, 475; poisoning, fatal case of, 243.
Cod-liver oil, alkaloids of, 160.
Coe, Dr. Henry C., the early recognition of cancer of the cervix uteri, 149; the immediate application of forceps to the after-coming head in cases of version with partial dilatation of the cervix, 63.
Cold-bath treatment of typhoid fever, 182.
Colds, and clothing, 391; the utility of, 242.
Cold-water treatment of typhoid fever, 434.
Colectomy *vs.* colotomy in malignant disease of the intestine, 335.
Colic, renal, in children, 125.
Colitis, croupous, 444.
College of Physicians of Philadelphia, Jenks prize, 243.
Color-sense, highly developed, of the people of India, 386.
Colotomy, inguinal, 193.
Coma, diabetic, relation of acetonuria to, 127.
Comma-bacillus and creoline, 46.
Competitive examinations, 324.
Compresses, very hot, in surgical practice, 122.
Concussion of the spine, 407.
Congenital malformations in an ancient Egyptian, 560.
Conjunctiva, nitrate of silver staining of the, 389.
Conjunctivitis, purulent, of infants, and blindness in the State of New York, 157.
Connecticut State Medical Society, 641.
Consanguineous marriages, 672.
Conservatism in minor surgery, with special reference to injuries of the fingers, 377.
Constipation, chronic, treatment of, by electricity, 156; stretching the sphincter ani for, 261, 273.
Consumption, pulmonary, as a neurosis, 351.
Consumptive travellers, 182, 355.
Contagious diseases, weekly statement, 28, 56, 112, 167, 195, 224, 252, 280, 308, 364, 391, 420, 448, 476, 503, 530, 558, 616, 643, 670, 699.
Contagiousness, duration of, 195.
Continence, as a preventive of syphilis, 463.
Continental Anglo-American Medical Society, 496.
Contributions to clinical and practical medicine, book notice, 102.
Cornea, periodical neuralgia of the, 285; transplantation of a rabbit's, into the human eye, 13.
Corning, Dr. J. Leonard, notice of book by, 578.
Corns, treatment of, 376.
Correspondents, a few words with our, 325.
Coryza, simple treatment for, 440.
Cough, mixture for, 28.
Counter-prescribing evil, 494.
Courts, medical cases in the, 368; medico-legal cases in the, 180.
Cramp, flute-players', 649.
Cranial measurements in infantile cerebral hemiplegia, 157.
Cranio-cerebral topography, 29.
Craniotomy, the question of, 323.
Creasote, carbonic acid water as a vehicle for, 231; in cancer, 95; in the treatment of phthisis pulmonalis, 45.
Cremation in Europe, 152.
Creoline and the comma-bacillus, 46; in the treatment of infectious throat diseases, 65.
Crepitant râle, significance of the, 510, 529
Crime, physiology and pathogenesis of, 548.
Crimes of alcoholism and unchastity, 615.
Cripps, Mr. Harrison, notice of book by, 101.
Cronin, Dr., death of, 661.
Croup, large doses of calomel in, 291.
Croupous pneumonia, etiology of, 309.
Crow, Dr. J. T., a modified Scudder's knottier, 503.
Cupping-glasses, as diagnostic and therapeutic means, 92; in depressed fracture of the skull, 532; use of, in diagnosis and therapeutics, 166.
Curette in puerperal endometritis, 291.
Cutaneous swelling and menstruation, 224.
Cutler, Dr. Condict W., notice of book by, 578.
Cycling as a therapeutic agent, 216.
Cyclitis, syphilitic, 641.
Cyst, dermoid, of the ovary, 359; of the mesentery, removal of, 68.
Cystic tumors, treatment of, 472.
Cystitis in women, rapid cure of, 574.
Cystotomy, supra-pubic, for removal of a calculus in a man seventy-nine years old, 274; supra-pubic, in obstructive senile hypertrophy of the prostate gland, 266.
Czar's physicians, the, 644.

D

Dalton, Dr. John C., 183; and the New York Pathological Society, 262; obituary notice, 186; resolutions on the death of, 336.
Dana, Dr. C. L., on cranio-cerebral topography, 29; the treatment of locomotor ataxia and other spinal diseases by suspension, 419.
Danger of reporting strange cases, 531.
Dartmouth, a hospital for, 635.
Darwin consults a doctor, 378.
Davis, Dr. N. S., Jr., the mode of action and value of antipyrin in typhoid fever, 66.
Dawbarn, Dr. Robert H. M., a successful case of immediate resection of the intestine for gangrene, 428.
Dead, disposal of the, 53.
Deaf-mutes, legal relations of, to the hearing community, 368.
Death, among the gouty, causes of, 353; apparent, causes of, 632; by decapitation, 18; electricity as a test for, 418; in a cataleptic state, 575; in the schools, 353; rigidity as a sign of, 419; sudden, causes of, 88, 108; sudden, from strangulation by meat, 445; sudden, in acute nephritis, 332; sudden, in chronic diseases, 112.
Death-rate in England, 249.
Decapitation, death by, 18.
Decatur, Ala., yellow fever epidemic at, in 1888, 620.
Degeneration, amyloid, recent studies in, 211.
Delirium, traumatic, 446.
Dentistry, practice of, hampered by patents, 352.
Dermoid cyst of the ovary, 359.
Dessar, Dr. Leonard A., a nasal douche cup, 280.
Diabetes and tumors, coincidence of, 515; lime-water in, 328; soya bread in, 386; surgical aspects of, 97; the kidneys in, 671.
Diabetics, bread for, 363.
Diagnosis, physical, application of acoustics of the human chest in, 158.
Diagnostic sign of hernia, 355; significance of tremor, 343.
Diaphragm and pleural cavity, aspirator needle plunged through the, into the liver, with fatal effect, 267.
Diarrhœa, chronic, treatment of, 371; fetid, treatment of, 56; hysterionica baylahnen in, 327; summer, 690; summer, in infants, prevention of, 156; summer, of children, 234.
Diet, in the treatment of Bright's disease, 1, 21.
Diffusion, anodal, 471.
Digestion, influence of drugs on, 294.
Dilatation of the stomach, rare case of, 349.
Diphtheria, a new study of the etiology of, 544; creolin in, 65; laryngeal, without croupy symptoms, 302; latest new treatment for, 271; local treatment of, 668; microbe of, 244; municipal control of, 156; primary nasal, in children, 94.
Diphtheritic paralysis, fatal case of, 543.
Diplomas, restricting endorsement of, 158.
Disease, communicated from the human to the lower animal, 278; of the lower animals, commission to study the treatment of, 307.
Diseases, rare, clinical uses of, 669.
Disinfection, by boiling water, 168; of the respiratory passages with myrthol, 379.
Dislocation, subcoracoid, of the humerus, Kocher's method of reducing, 337.
Dispensatory of the United States of America, book notice, 577.
Doctor, summoning the, with a cannon, 672; the privilege of being a, 62.
D'Oench, Dr. F. E., a peculiar case of detachment of the retina, 268; white spots in the retina, 669.
Donders, Franciscus Cornelis, Feest Bundel aan, book notice, 186.
Donders, Professor F. C., death of, 356.
Drainage and drainage-tubes in their application to the treatment of wounds, 605.
Drugs, the best twenty-five, 74, 194.
Drunaine, 466.
Dry cups, in depressed fracture of the skull, 532; use of, in diagnosis and therapeutics, 92, 166.
Drzewiecki, Dr. Joseph, antirabic inoculations an unscientific method in the prevention of hydrophobia, 645.
Dudley, Dr. W. H., albinismus, 292.
Dumond, Dr. M. A., placenta prævia with spontaneous arrest of hemorrhage, 377
Duodenum, congenital occlusion of the, 320.
Duprat, M., death of, 660.
Dupuytren's finger-contraction, 82.
Dust, inhalation of, as a cause of pulmonary phthisis, 549, 554.
Duval, Dr. E., notice of book by, 102.
Dysentery, hysterionica baylahnen in, 327.
Dysmenorrhœa, medicinal treatment of, 129.
Dyspepsia, 638; water in, 162.
Dysphonia spastica, 665.

E

Ear disease, dangers of, 69; the, and its diseases, book notice, 300.
Echinococcus cysts of the liver, 444.
Eclampsia infantum in its relation to fever, 58, 163; puerperal, etiology of, 689.
Eddy, Dr. Joseph W., a modified Allis' ether inhaler, 530.
Edinburgh Medical Missionary Society, 436.
Edson, Dr. Cyrus, the poison of typhoid fever, 9.
Education, medical, and its control by medical parliaments, 689.
Effeminacy and anæsthetics, 44.
Eichberg, Dr. Joseph, another sign of intestinal perforation, 556; intubation twice successfully performed in the same patient, 348.
Einhorn, Dr. Max, the behavior of hydrochloric acid in the stomach of phthisical patients, 483.
Electric cataphoresis as a therapeutic measure, 471.
Electrical instruments used in the United States, 196.
Electricity, as a test for death, 418; effects of, on central nervous diseases, 387; effects of, in functional nerve affections, 388; effects of, in peripheral nerve lesions, 388, 475; effects of, in spinal cord diseases, 388; in gastric dilatation, 407; in fibroid tumors of the uterus, 639; in gynecology, 550; in the treatment of chronic constipation, 156; in the treatment of uterine fibroma, 379, 389; in therapeutics, value of, 387, 390; physics and physiological actions of, 387; relative influence of primary and

induced currents over muscular contractions in paralysis, 475; uses of, in medicine, 362; value of, in therapeutics, 382.
Electrolysis in angioma and goitre, 181; in stricture of the œsophagus; 383, 418, 495; in urethral stricture, 221, 277, 418, 670; of the Eustachian tube, 476.
Elements of practical medicine, book notice, 467.
Elephantiasis in the Samoan Islands, 383.
Ellis, Dr. Richard, early experiments with nitrous oxide, 436.
Ely, Dr. John S., a case of malignant endocarditis, infection apparently from urethritis, 287; aneurism of the arch of the aorta; sudden death without rupture of the sac; remarks on the causes of sudden death, 88.
Emanuel Sisterhood of Personal Service, 603.
Embalming, Brunelli process of, 356.
Embolic pneumonia, 156.
Embryos, early twin, 531.
Emmerton, Dr. James A., death of, 47.
Emphysema, interlobular pulmonary, 108, 192.
Encephalic fœtus, 359.
Encephalitis and epilepsy following compound depressed fracture of the frontal bone, 179, 190.
Endocarditis, acute ulcerative, limited to the tricuspid valve, 90; an early sign of, 352; following chorea, 68; malignant; infection apparently from urethritis, 287; ulcerative, 25.
Endometritis, puerperal, the curette in, 52, 291, 639.
England, death-rate in, 249; marriage and birth statistics in, 453.
Entwickelung, die, der Bakterienfärbung, book notice, 300.
Epilepsy, following compound depressed fracture of the frontal bone, 179, 190; simulo as a remedy in, 512, 529; traumatic, 613; with olfactory aura, 305.
Epithelioma of the soft palate, 414.
Ergot, in incontinence of urine in children, 15; in threatened heart failure in children, 239.
Erysipelas, treatment of, 568.
Eschscholtzia californica, 48, 214.
Essentials of physics and chemistry, book notice, 578.
Ether, inhaler, a modified Allis', 530; new use for, during anæsthesia, 14.
Etherization, abuse of, a plea for the junior assistant, 277; mania following, 218; some of the abuses of, 205, 217.
Eustachian tube, electrolysis of the, 476.
Evans, Dr. Francis J., death of, 299.
Everitt, Dr. Daniel L., death of, 131.
Examination for hospital appointment, a unique, 556.
Examinations, competitive, 324.
Examiners, State Boards of, 548.
Exhaustion, nervous, and cancer, 519.
Exophthalmic goitre, pathology of, 634.
Exophthalmos caused by intra-nasal operations with the galvano-cautery, 614.
Exostosis bursata, 406.
Expert testimony, medical, 144.
Exploration of the chest in health and disease, book notice, 524.
Extra-uterine pregnancy, early diagnosis of, 699; with delivery of the fœtus intact per rectum, 78.
Eye, extraction of cataract, 357; extraction of hard cataract, 340.
Eyeball, dislocation of the, 509; enucleation of the, 532.
Eyesight of school-children, 616.
Eye-strain as a cause of headache and neuralgia, 673.

F

Family physicians, a charge against, 76.
Fat-necrosis of the pancreas, 197.
Fatty degeneration of the vitreous body, 569.
Fatty tumor, non-capsulated, of the neck, removal of, 487.
Fecundity, and age, 56; remarkable instance of, 644.
Fee, a large, 495; the physician's, 520.
Feeding, artificial, in children, 234: forcible, a simple method of, 82.
Feet, sweating of, boric acid for, 128.
Fenwick, Dr. E. Murry, notice of book by, 300.
Fenwick, Dr. K. N., notice of book by, 578.
Fever, a new specific, 520; chronic intermittent, of severe type and unknown origin, 399, 413; eclampsia infantum in its relation to, 58, 163; syphilitic, 700; syphilitic, nine years after infection, 555.
Fever-ferment, a, 492.
Fevers, clinical instruction on, 193; specific, abortive treatment of, 324.
Fibroid tumor, submucous, of the uterus, 245; of the uterus, electrolysis in, 639; of the uterus, relation of, to the organization of thrombi, 640.
Fibro-sarcomata of the uterus and liver, 329.
Fingers, injuries of, conservatism in, 377.
Fissure, anal, spasmodic urethral stricture from, 85, 105.
Fistula, cervico-thoracic, 104; in ano in the female, operated on by suturing, 485; in ano, restoration of the sphincter, 80; in ano, treatment of, 169.
Fitz, Dr. Reginald H., acute pancreatitis, 197, 225, 253.
Flannel, use of, in gastro-intestinal disorders of children, 236.
Flood, Dr. Henry, a new anæsthetic inhaler, 642.
Flute-players' cramp, 649.
Fœtal membranes, early rupture of, with continuance of pregnancy, 655.
Fœtus, a young living, 656; blood of, at birth, 560; encephalic, 359.
Food adulteration in Paris, 473.
Forceps, as a cause of idiocy, 349; for refracture of the nasal septum, 111; immediate application of, to the after-coming head, in cases of version, 63, 80.
Forest, Dr. W. E., the cost of yellow fever epidemics—the epidemic at Decatur, Ala., in 1888, 620.
Foster, Dr. Frank P., notice of book by, 101.
Foster, Dr. M., notice of book by, 468.
Fowls, tuberculosis of, 408.
Fracture, compound depressed, of the frontal bone, 179, 190; compound, of the os calcis, primary union of, 80; compound, of the skull, 362; of the head of the humerus, due to muscular action, 209; of the spine, book notice, 524; of the symphysis pubis during labor, 364; spontaneous, of a sarcomatous tibia followed by bony union, 371.
France, suicide in, 267.
Free, Dr. Spencer M., the twenty-five best drugs, 194.
French Hospital, the, 644.
Friedreich's disease, suspension in the treatment of, 251.
Frissell, Dr. John, Dr. Alonzo Clark and microscopy; a reminiscence by one of his class-mates, 305.
Frog, skin of, zoöplastic graftings with, 473.
Frontal bone, compound depressed fracture of, 179, 190.
Frost, Mr. William A., notice of book by, 185.
Frost-bites, treatment of, 174.
Fruitnight, Dr. J. Henry, urinary concretions in children, 122.
Fullerton, Dr. O. J., conservatism in minor surgery, with special reference to injuries of the fingers, 377.

G

Gall-stones, olive-oil treatment of, 518, 599.
Galvanism in gynecology, 159.
Gangrene, pulmonary, myrtol in, 243.
Gastric juice, acid principle of the, 70; mucous membrane, atrophy of, 631; ulcer, an enormous, with gastritis, 273.
Gastro-intestinal catarrh, chronic, notes regarding the management of, 263; disorders in children, 234; fermentation, auto-infection from, 133.
Gastrotomy for removal of a spoon, 166.
Generative organs, female, mycology of, in health, 410.
Genito-urinary tract, primary tuberculosis of, 105.
German Dermatological Association, organization of, 384.
German Surgical Congress, work of the, 575.
Gerrish, Dr. Frederick Henry, notice of book by, 102.
Gerster, Dr. Arpad G., removal of a tubercular tumor of the larynx by laryngo-pharyngotomy, with demonstration of cases, 365, 414.
Gestation, prolonged, 547.
Giant, an acromegalous, 244.
Gibbes, Dr. Heneage, chondroma, 86.
Gibney, Dr. V. P., spondylolisthesis of traumatic origin, 347.
Girdner, Dr. William, obituary of, 440.
Gish, Dr. John L., cure of œsophageal stricture, 495.
Gluck, Dr. Isidor, membranous rhinitis, 461.
Glycerine, increase of vaginal secretions from, 54.
Goitre, electrolysis in, 181; exophthalmic, pathology of, 634; extirpation of, 130.
Goldsmith (Middleton) Lecture for 1889, 197, 225, 253.
Gonorrhœa, a new method of treating, 64; in women, 407; thallin in the treatment of, 380.
Good form and English medical men, 17, 20, 249.
Goodwillie, Dr. Thomas, death of, 48.
Gouty, causes of death among the, 353.
Gowers, Dr. W. R., notice of book by, 468.
Greek letter medical society, 299, 439.
Greene, Dr. C. A., the crimes of alcoholism and unchastity, 615.
Greene, Dr. J. H., concerning rheumatic peritonitis, 110.
Gross, Dr. R., maternal impressions, 43.
Gross, Dr. Samuel W., death of, 560; obituary notice of, 440; resolutions on the death of, 606.
Growth of the child's mind, 573.
Growths, morbid, early diagnosis of, 584.
Gum chewing and the eyes, 69.
Gunshot wounds of the abdomen, 604.
Gynecological operations, acute mania and melancholia or hypochondriasis as sequelæ of, 441, 446.
Gynecology, electricity in, 159, 550.

H

Hæmatoma of both ovaries, 79.
Hæmatozoon, an alleged, of relapsing fever, 490.
Hair, nodosity of the, 375.
Hall, Dr. George D., a new polypus snare, 530.
Hansen, Dr. C. M., the curette in puerperal endometritis, 291.
Harvey, Dr. J. G., prenatal circumcision, 335.
Hasbrouck, Dr. Josiah, death of, 512.
Haven, Dr. A. C., the physical perfection of man, 83.
Hawaiian, physical constitution of the, 473.
Hay-fever, cocaine in, warning against the use of, 392.
Headache, and its relation to the retention of uric acid, 353; chronic, 159; eye-strain as a cause of, 673; nervous, 611.
Healthy city in an unsanitary condition, 98.
Hearing, tests of, for locomotive engineers, 609.
Heart, acute ulcerative endocarditis limited to the tricuspid valve, 90; apex, position of the, 274; dilatation of, management of, 158; diseases of the, Germain Sée on, 559; murmurs, physiological (endocardial) mechanism of, 421; muscle, peculiar tumor of the, 106; paralysis of, as a cause of sudden death, 88; sounds when the breath is held, 570

Heath, Mr. Christopher, notice of book by, 468.
Hemiplegia, infantile cerebral, cranial measurements in, 157.
Hæmoptysis, atropine in, 243; treatment of, 547.
Hemorrhage, cerebral, trephining for, 613; pancreatic, 197; pulmonary, atropine in, 243; torsion of arteries for the arrest of, 606; water in, 161.
Hæmorrhoids, ligation in the treatment of, 286.
Heredity and alcoholism, 571.
Hernia, gangrenous, surgical treatment of, 583; inguinal, radical cure of, 312, 330; new diagnostic sign of, 355; of the pleura in the neck, 159; radical cure of, 581; recent advances in the treatment of, 187.
Hinde, Dr. Alfred, a new palate-retractor, 364.
Hip-joint disease, 24; early excision in, 53; management of, from an anatomico-pathological basis, 477; specimens of, 501.
Holden, Dr. Edgar, a new instrument for tracheotomy, 194.
Holmes, Dr. Oliver Wendell, love for his books, 183.
Homœopathist, a judge's opinion on the use of the title of, 504.
Hope, Dr. George B., forceps for refracture of the nasal septum, 111.
Hospital, accommodations in new York, 295; an imitation, 566; collection fund, distribution of, 355; extravagance, an attack on, 83; surgeons and payment for operations, 573.
Hospital Graduates Club, 576.
Hospitals in New York State, 215.
Hot drinks, disadvantages of, 55.
Howard, Dr. R. P., obituary of, 384.
Howard's method of treating suspended animation from a clinical standpoint, 306.
Huckins, Dr. Payson T., a unique non-capsulated fatty tumor of the neck—removal, with ligation of all the jugular veins except the left internal—recovery, 487.
Human body, electrical state of, in health and disease, 389.
Hume, Dr. William A., compound depressed fracture and loss of substance of the frontal bone—encephalitis—epilepsy—death, 179.
Humerus, fracture of head of, due to muscular action, 209; subcoracoid dislocation of, Kocher's method of reducing, 337; subspinous dislocation of, reduced after five months, with good results, 377.
Hunter, Dr. James B., obituary of, 661; the menopause in some of its relations to disease, 57; the technique of vaginal hysterectomy, 147.
Hunterian oration, 304; orations, 272.
Hutton, Dr. T. J., some defensive remarks on the climate of Minnesota, 370.
Hydatid cyst of right kidney, 541.
Hydrocephalus, puncture in, 364.
Hydrochloric acid, behavior of, in the stomach of phthisical patients, 483; cause of diminution of, in gastric carcinoma, 654; presence of, in seasickness, 484.
Hydronephrosis, intermittent, 95.
Hydropathic treatment of typhoid fever, 156.
Hydrophobia, 551; antirabic inoculations an unscientific method in the prevention of, 645; palace of, and Pasteurism, 269; editorial on, 729.
Hydro-pneumo-thorax, 77.
Hydroxylamine in skin diseases, 630.
Hymen, the, in the negress, 214.
Hyperostosis of the external auditory canal, 187.
Hypnotic, uralium a new, 384.
Hypnotism, dangers and uses of, 109.
Hypochondriasis following gynecological operations, 441, 446.
Hysterectomy, vaginal, 639; vaginal, for carcinoma uteri, 43; vaginal, technique of, 147, 157.
Hysteria, and epilepsy, book notice, 578; in the Russian army, 504.
Hysterionica baylahnen, 327.

I

Ice-water, a word for, 54.
Idiocy, is instrumental delivery a cause of? 349.
Illegitimacy, promotion of, in Vienna, 670.
Illinois State Medical Society, 637.
Illumination of cavities, a new method of, 244.
Importing doctors, 353.
Incontinence of urine in children, ergot in, 15.
Incubation and contagiousness, duration of, 195.
Index catalogue of the library of the surgeon-general's office, U. S. A., book notice, 102.
Indiana State Medical Society, 609.
Inebriety, diagnosis of, 94; in the educated classes, treatment of, 462; its cause, its results, its remedy, book notice, 468; medical view of, 157.
Infant, amputation of the thigh in an, 461; foods, a trial of, in the babies' hospital, 234; mortality and its relations to pulmonary tuberculosis, 110.
Infantile cerebral hemiplegia, cranial measurements in, 157; paralysis, "dangle-leg," due to; anchylosis of the knee as a remedy for, 367.
Infants, eclampsia of, in its relation to fever, 163; purulent conjunctivitis of, and blindness in the State of New York, 157; septic poisoning in, 161; summer diarrhœa in, prevention of, 156; thirst in, 434; washing out the stomach in, 212, 276.
Infection, the nail-brush as a source of, 28.
Infectious disease, a new, 154; diseases, the notification of, and imprisonment of physicians, 728.
Inflammation and microbes, 380.
Inguinal hernia, radical cure of, 312, 330.
Inhaler, an improved nasal, 390, 414.
Injections, intra-uterine, accidents due to, 391.
Insanity, and marriage, 600; and race, 15; increase of, 574; increase of, in New York State, 20.
Insolation in a young child, 328.
Insomnia, peanuts for, 504.
Insufflator and tongue-depressor, 364.
Intercolonial Medical Congress in Australia, 272.
